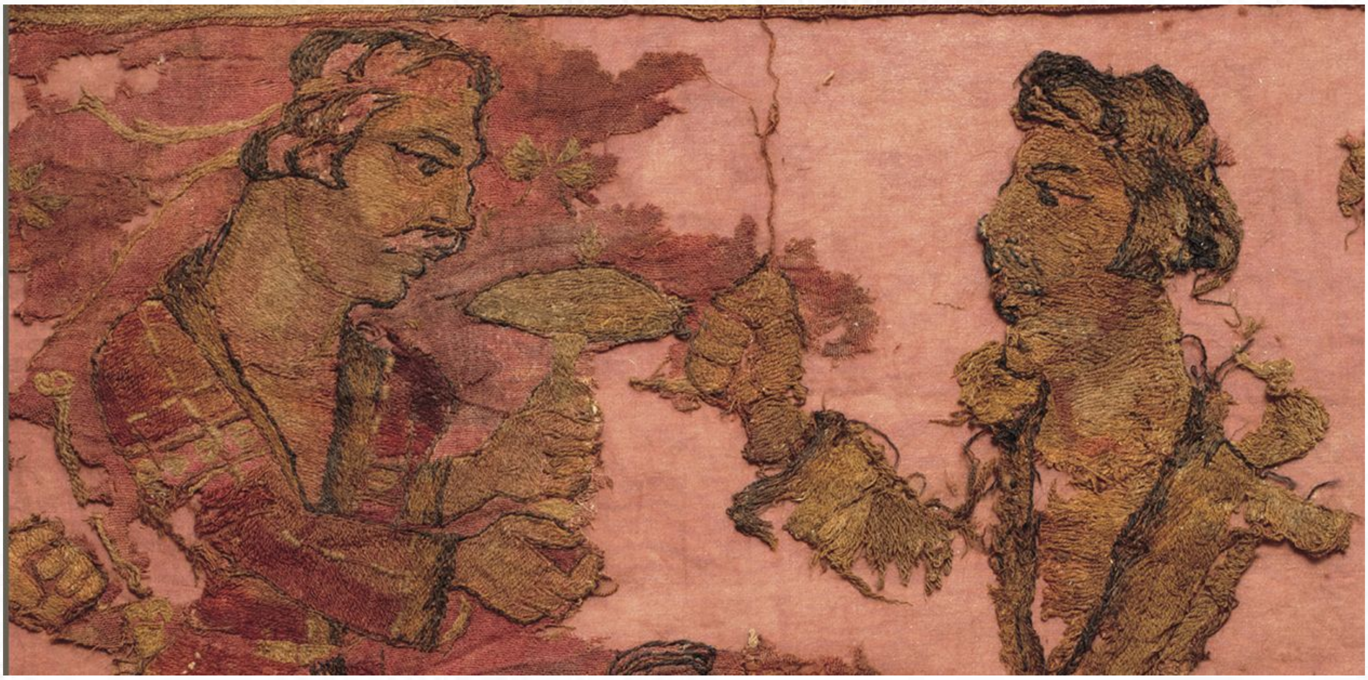
Natalia V. POLOSMAK, Doctor of History, chief researcher at the Institute of Archaeology and Ethnography SB RAS (Novosibirsk). Laureate of the Russian State Prize, Legacy of Generations National Prize, Corresponding Member of the German Archaeological Institute, Director of Honor of the Institute of Archaeology of Mongolia. She is the author and co-author of over 130 academic works including 12 books.



[Abstract]

Inside a deep Xiongnu grave hidden in the thickly wooded Sudzuktè pass, on the bottom of the burial chamber, archaeologists, participants of the Russian-Mongolian expedition, found what they had long been searching for: a layer of clay revealing the outline of textile relics. The fragments of the textile found were parts of a carpet composed of several cloths of dark-red woolen fabric. The time-worn cloth found on the floor covered with blue clay of the Xiongnu burial chamber and brought back to life by restorers has a long and complicated story. It was made someplace in Syria or Palestine, embroidered, probably, in north-western India and found in Mongolia.

Finding it two thousand years later is a pure chance; its amazingly good condition is almost a miracle. How it made its way to the grave of a person it was not meant for will long, if not forever, remain a mystery. Of greatest surprise though was the unique embroidery made from wool. Its pattern was the ancient Zoroastrian ceremony, of which the principal personage was ...a mushroom. In the center of the composition to the left of the altar is the king (priest), who is holding a mushroom over the fire. The «divine mushroom» embroidered on the carpet resembles well-known psychoactive species *Psilocybe cubensis*.

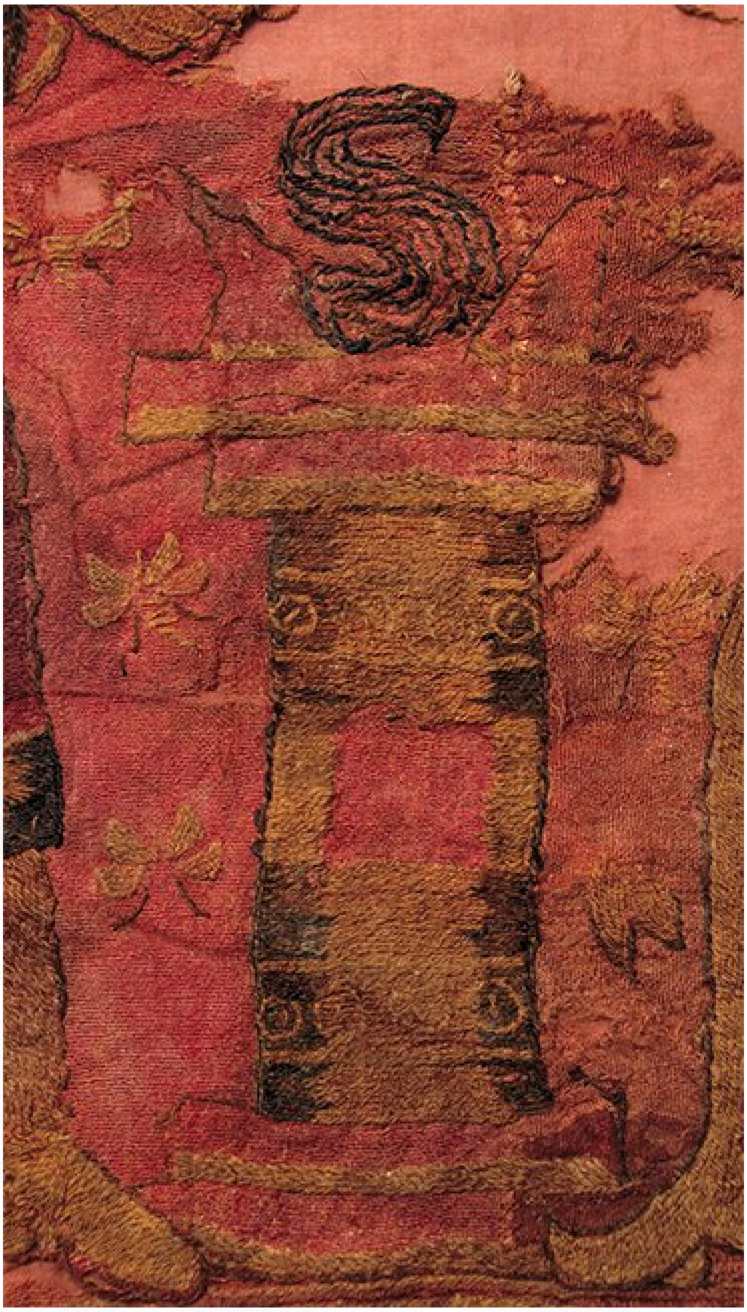
The weight of evidence suggests that soma, the ancient ritual drink, has been prepared from the mushrooms of family Strophariaceae which contain the unique nervous system stimulator psilocybin.

Keywords: ancient textiles, Xiongnu, Divine mushroom, soma/haoma, Indo-Scythians, Indo-Parthians, psilocybin, North Mongolia

Diggings of 31 Xiongnu tumuli (dated from the late 1st c. B.C. to the early 1st c. AD) of the Noin-Ula burial ground (Mongolia) carried out in 2009 by an expedition of the Institute of Archaeography and Ethnography, Siberian Branch of the Russian Academy of Sciences (SB RAS), have discovered embroidered woolen textiles preserved by a miracle. Their complete restoration is a long way to go; however, the first fragments restored have revealed exceptional information.

Inside a deep Xiongnu grave hidden in the thickly wooded Sudzuktè pass, on the bottom of the burial chamber, archaeologists found what they had long been searching for: a layer of clay revealing the outline of textile relics.

This was the third find to date; all of them were made in the well-known Xiongnu burial ground of Noin-Ula: the first fragments of a unique textile were found here as early as in the 1920s by the expedition of the eminent traveler and scholar P. K. Kozlov. Like many other things, the precious fabrics happened to be in the graves of rich nomads because of the trade along the Silk Road. Xiongnu did not participate in the trade deals but they controlled a long stretch of this perennial spring of foreign goods.



On the altar the flame burns - two tongues on the sides and an S-shaped sign in the middle. The flame of king's fireplace mounted on the altar is a symbol of royal grandeur.

Basing on the first find, the researchers believed that the textile from the Xiongnu burial ground was made in Bactria (Pugachenkova, 1966). However, the finds made in 2006 and 2009 do not allow identifying this textile so unambiguously. Of greatest surprise though was the find made in 2009, or, to be more exact, the unusual pattern involving people and animals embroidered on the textile.

The fragments of the textile found were parts of a carpet composed of several cloths of dark-red woolen fabric. The fabric itself must have been meant for mantles. A sign of this is the narrow maroon woven stripes with "pockets." These important ornamental details are known not only from the numerous finds of real textiles in Dura-Europos, Syria, in Palmira and in the Palestinian Cave of Letters, but also from frescos, paintings on Egyptian sarcophagi, and early Christian mosaics (Yadin, 1963).

Similarly to the known mantle textile, the woven stripes of the Xiongnu find do not go from one edge to the other but begin and end within a single cloth. Their cut bits were sewn together without taking into account the location of woven stripes: the ornamental element, so important for making mantles, this time proved to be unnoticed.

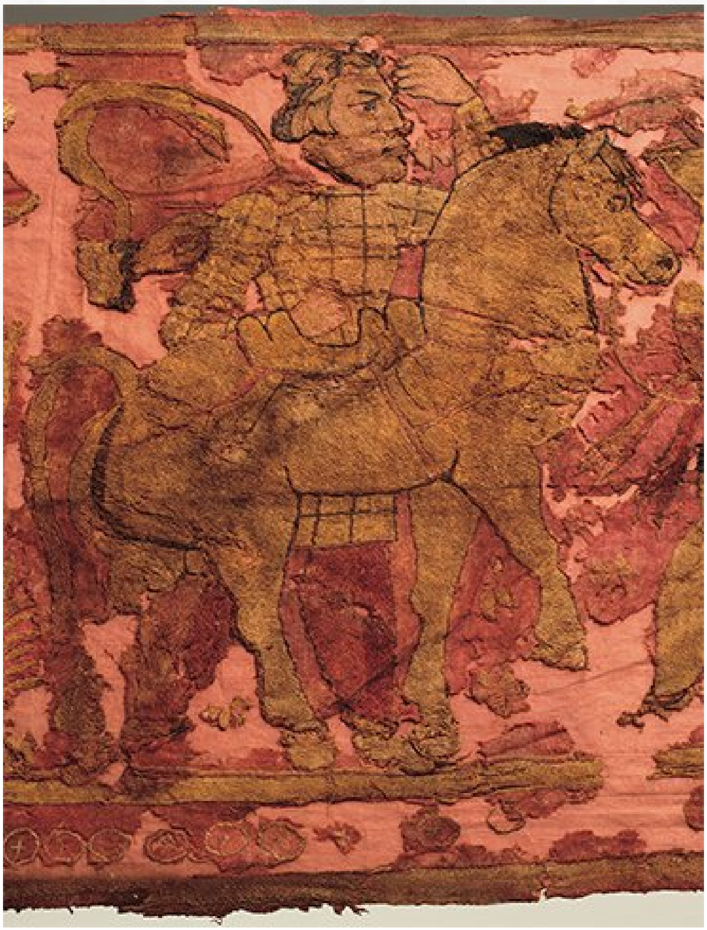
The embroidered fabric filled the narrow space between the chamber's wooden walls and the coffin, which was placed in the middle on another, not embroidered textile. As a matter of fact, the embroidered carpet was laid along the corridor used for the burial ceremony. On top of the fabric was a thick layer of blue clay brought on purpose, which, according to the Chinese tradition was used to make the chamber waterproof. This clay cover made the restorers' work very hard but preserved the textile.

Beside the altar flame

The restorers' hands have revealed the following embroidered plot: a procession to the altar. The altar itself - support for the fire - is a column with a base consisting of two steps and a two-step top turned upside-down. The column shows depictions of circles with a dot in the center - the widespread ancient symbol of fire and the Sun. In the Achaemenid time, similar altars were a novelty introduced by Persians, who proclaimed their adherence to the Zoroastrian belief. "The flame of the king's fireplace, going upwards in this way, became a symbol of their grandeur." (Boyce, 1988, p. 75 - 76).

The altar is aglow with the fire. These Zoroastrian fires had a martial spirit: those who prayed to them were warriors fighting on the side of good creatures against gloom and cold, evil and ignorance.

...Men are approaching the fire. They are armed with daggers attached to the right thigh and long swords with a ring or round pommel and long grip appended to the belt on the left. The warriors are wearing Iranian garments - red trousers, narrow or loose, and closely fitting jackets, wrapped on the left, or longer kaftans. The dress is girdled with a buckled belt and lined with fur.

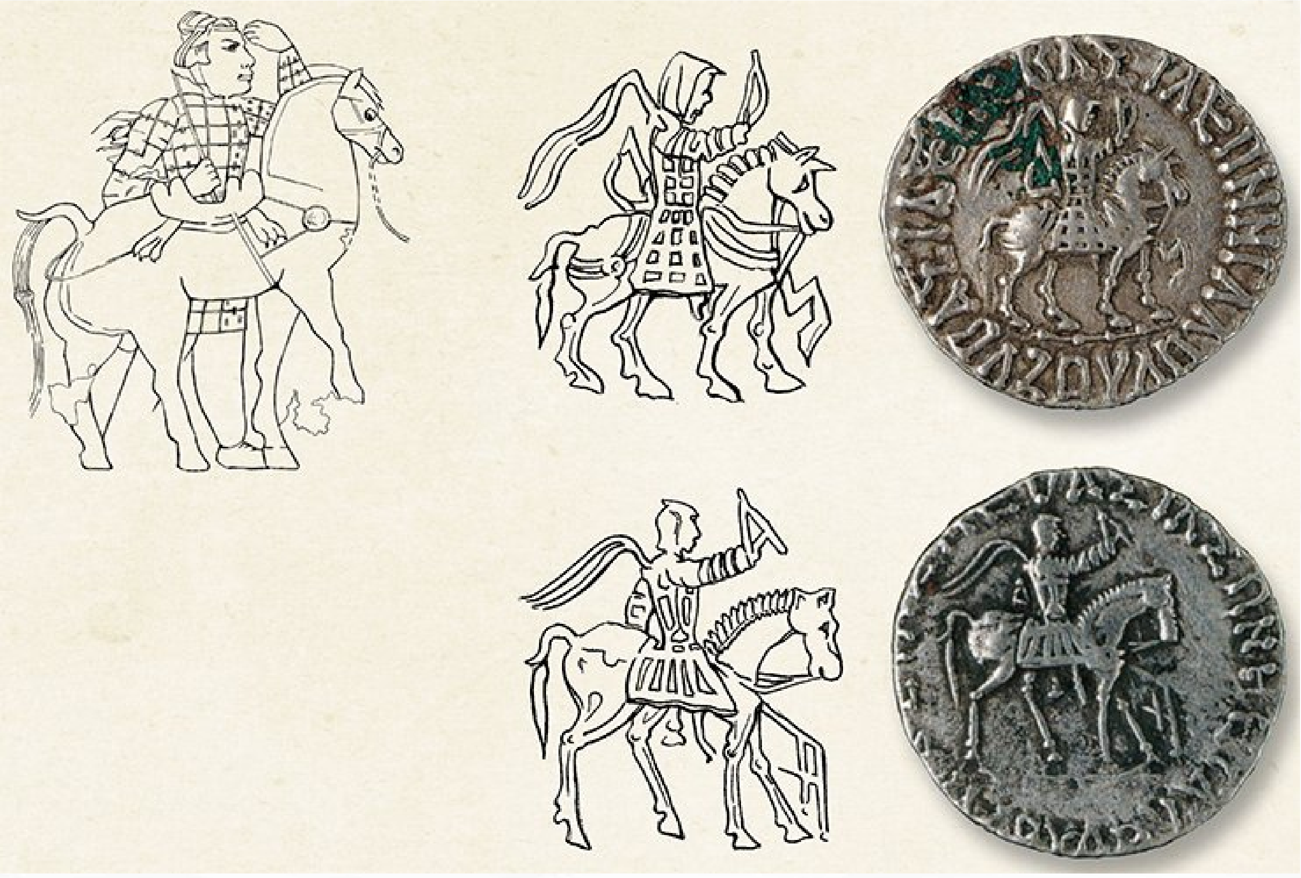


Men in Iranian dress, equipped with daggers and long swords, approach the fire.

The warriors' black voluminous tresses, set in rows and cut at the length of ear lobes, are sometimes strapped across the forehead with a narrow ribbon with fluttering ends. Their looks are conspicuous: expressive profiles of their broad round faces with big eyes, soft chins, pudgy lips and big, slightly aquiline noses. The faces are shaved, though many have a black narrow moustache above the upper lip.

A dismounted rider wearing an armor-clad long jacket with something like a scarf or a cloak fluttering behind his back attracts special attention. His beardless face is stern. The left hand is raised to the forehead in a gesture of adoration common as early as during the Achaemenids as a sign of worshipping a deity. The rider's horse is held by the bridle by an armed man in a short jacket with something like a scrip on his back from which something like a mushroom is peeking out.

The manner in which the warrior with a horse is depicted copies in minute detail the images on the heads of the coins minted by Indo-Scythian (Saka) kings: Azes I, Aziles and Azis II, who governed north-western India approximately from 57 BC, as well as by their successor Gondofar, the first Indo-Parthian ruler of West and East Punjab (from 20 AD to 46 AD).



A dismounted rider wearing an armor-clad jacket raised his left hand to the forehead in the traditional Zoroastrian gesture - the sing of worshipping a deity (left). Drawing of the carpet by Ye. Shumakova. The depictions of embroidered riders on the carpet and rulers on the heads of Indo-Scythian coins have a great deal in common. On the right are the coins of Azes II, on the left is their drawing. From: (Musee National des Arts Asiatiques-Guimet - l'Asie des steppes d'Alexandre le Grand à Gengis Khan, 2000)

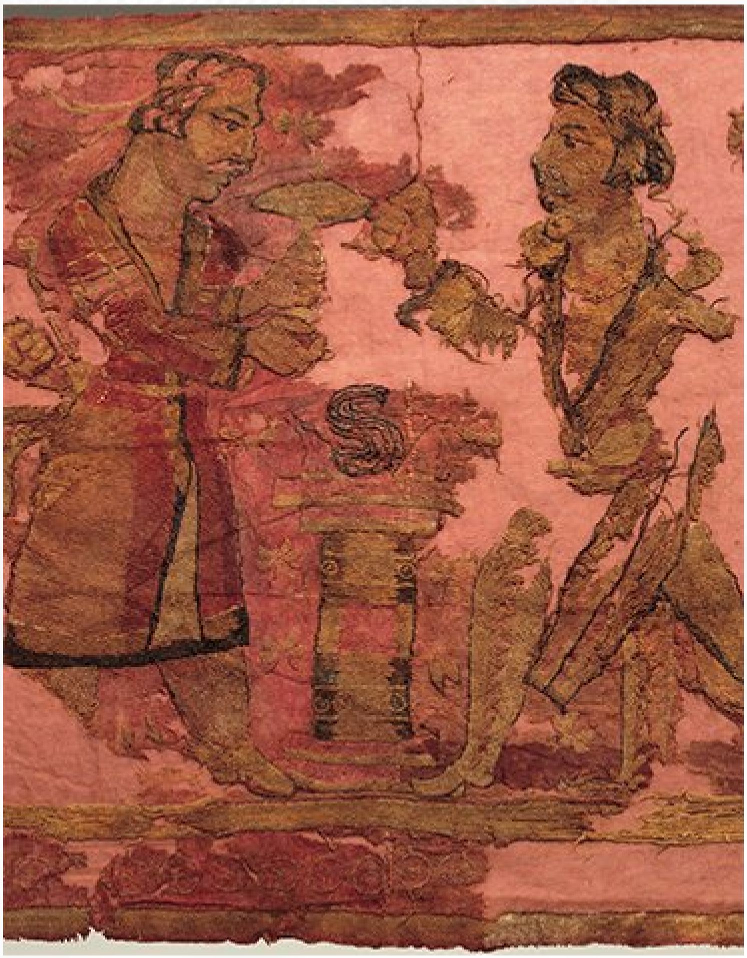
On these coins we can see similar stocky round horses with long tails and strapped docks, cut in a particular manner: a hogged plait at the tail head. Like the embroidered horse, their breast collars are decorated with plates.

The saddle with four horn-shaped supports is identical to the reconstruction made on the basis of Roman archaeological data (Connoli, 2001) with the only difference: instead of leather laces hanging down from under the saddle, there are two clawed paws of a predator's hide that was used as a horsecloth. These saddles are believed to have appeared by the beginning of the Parthian period and were widely spread with the Parthian cavalry; they were also known to the Sarmatians. Similarly to the embroidered warrior, the riders on the coins are wearing tight waist jackets sewn around with big rectangular plates - such armor was known to the Sakai and Parthians.

These similarities are an important argument in favor of the hypothesis that the carpet shows Indo-Scythians or Indo-Parthians.

Divine mushroom

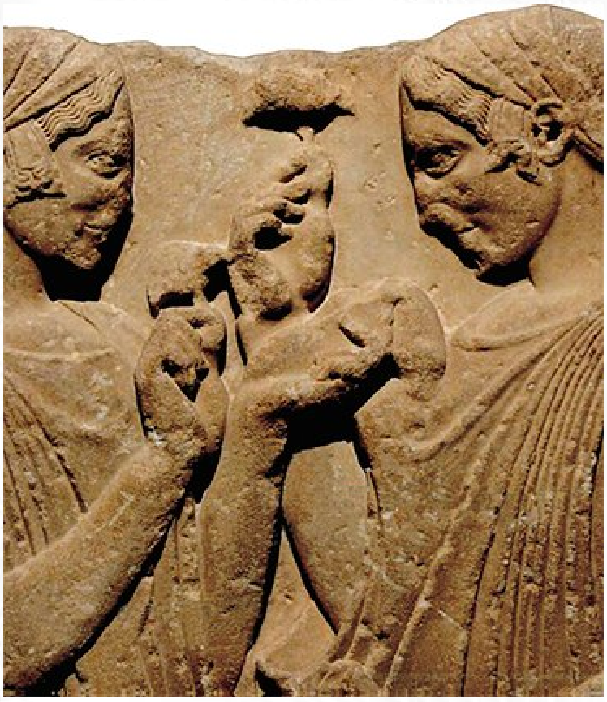
The embroidered plot develops further... We can see people standing absorbedly around the altar fire. The most prominent figure among them is the man on the left - probably, the king himself or a priest - dressed in a smart long embroidered kaftan gaping open at the bottom. He has a rarely expressive face, and his intent look is focused on the mushroom he is holding in both hands.



To the left of the altar is the king (priest), who is holding a mushroom over the fire. Opposite him is a warrior in a jacket with a "tail" and a belted quiver.

A priest with the Divine Mushroom in his hand... The question of what plant was used to prepare soma, or haoma - the drink of gods ancient Indians and Iranians imbibed has been debated for over a hundred years. Up to now, the plant whose sap was a permanent participant of the rituals, an offering to gods made by ancient Indians and Iranians, has not been identified. The hypotheses are plenty: from ephedra, cannabis, and opium poppy to oriental lotus (e.g., Abdullaev, 2009; McDonald, 2004; *et al*.). All researchers agree that ancient Indians and Iranians used for cult purposes a drink containing a psychoactive substance - it is only debatable what it was exactly and how it affected the people's consciousness.

The translator and greatest authority on the Rig-Veda (RV) T. Ya. Yelizarenkova wrote: "Judging by the RV hymns, Soma was not only a stimulating but a hallucinating drink. It is difficult to be more particular not only because none of the candidates satisfies all the soma properties and matches the soma descriptions found in the hymns only partially but primarily because the language and style of the RV as an archaic cult monument reflecting the poetic features of 'Indo-European poetic speech' is a formidable obstacle to soma identification. The answer may be provided by archaeologists and their finds in north-western India, Afghanistan, and Pakistan (and not in the far-away Central Asia)."



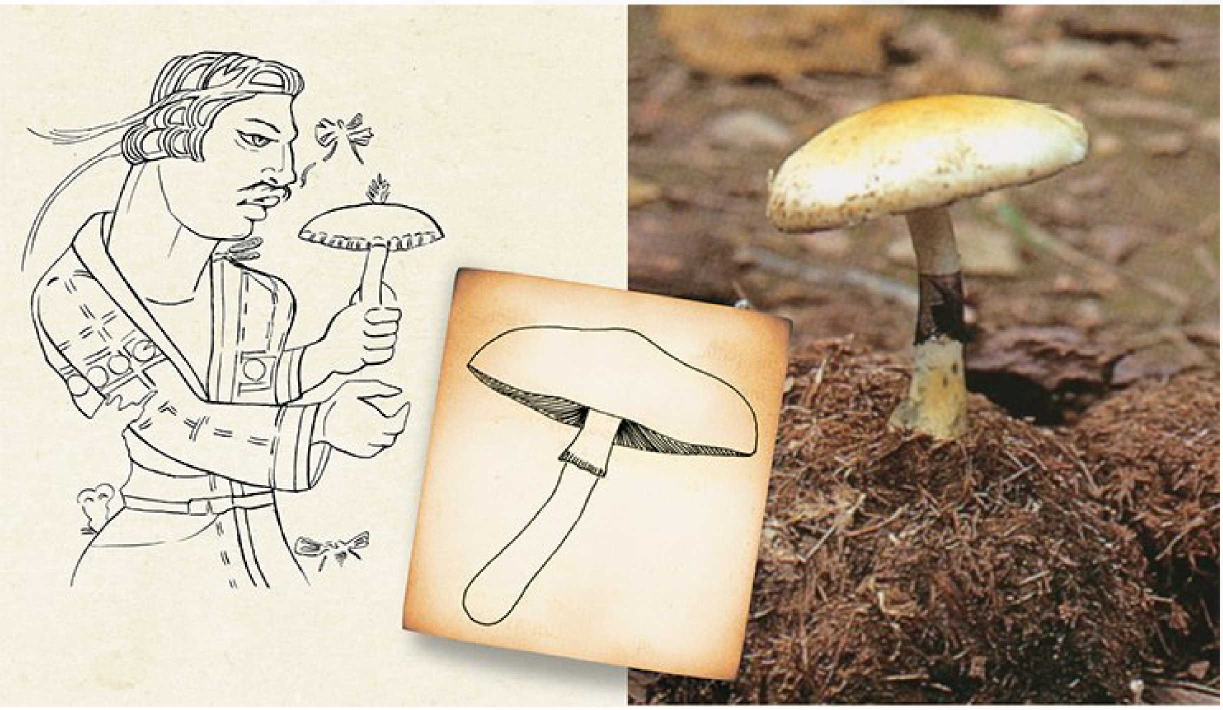
A scene from the Eleusinian Mysteries: Persephone taking a mushroom from Demeter. C. 4th c. BC.

The Eleusinian Mysteries were the oldest religious festivities held in ancient Greece and dedicated to Demeter and her daughter Persephone, spouse to the underworld ruler Hades. The participants of the Mysteries ritually went through death and rebirth. It is known that the initiates were promised rewards in the afterlife. Those who had experienced the mystical death firmly believed that for them a new life would begin after death. "Happy is he who has seen this before sinking into the grave: he knows the end of life and he knows its god-given beginning." (Pindar)

What particular rites made the initiates think of death with joy is not known. From of old, divulging the secret rituals was punishable by death. It is only known that the initiates were to live through and gain their own religious experience; there is evidence that the participants of the Mysteries had visions of images beyond thought. The prominent philosopher and Orientalist Ye. A. Torchinov puts it straightforwardly: "The Eleusis mystery is the mystery of psycho-technical experience of death and rebirth that purifies and integrates the myst psyche..." (1997, p. 145). To achieve this state, some hallucinogenic substances were used, maybe these contained in mushrooms.

This was written in 1999 - ten years before the outstanding find that testified that Indo-Scythians (Saka) and Indo-Parthians had used mushrooms for cult purposes.

The mushroom depicted on the Xiongnu carpet can belong to family Strophariaceae, according to Candidate of Biology I. A. Gorbunova (Laboratory of Inferior Plants, Central Siberian Botanical Garden, SB RAS, Novosibirsk). Its external appearance has similarities with species *Psilocybe cubensis* (Earle) Singer [= *Stropharia cubensis* Earle].



A priest with the divine mushroom in his hand. Drawn from the carpet by Ye. Shumakova. The "divine mushroom" embroidered on the carpet resembles *Psilocybe cubensis* in its habit, shape of the cap, and stitches along the cap margin that look like radial folding or veil remnant. Dark inclusions on the stalk may depict the annulus that blackens because of falling spores. The mushrooms of genus *Psilocybe*, like many other species of family *Strophariaceae*, contain the psychoactive substance psilocybin. On the left is a king/priest with a mushroom in his hand. Drawing of the carpet by Ye. Shumakova. On the right is the fruit body of *P. cubensis*, grown on elephant dung (India). From: (Stamets, 1996). In the center is a diagram of *P. cubensis* fruit body. From: (Guzmán, 1983)

Many species of family *Strophariaceae*, especially genus *Psilocybe*, contain psilocybin, a unique psychoactive substance and a nervous system stimulator. The mushrooms having this substance play the leading role in T. McKenna's psychedelic theory of evolution - one of the most original hypotheses of the origin of humans, their language, conscience, and culture.

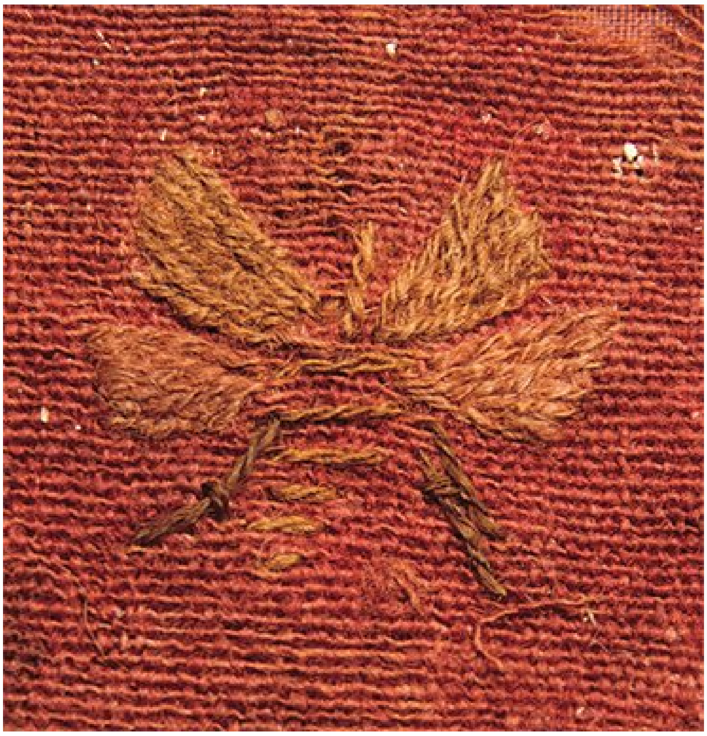
"Our remote ancestors discovered that some plants can suppress appetite, relieve pain, supply a sudden rush of energy and immunity towards pathogenic factors, as well as result in a synergy of cognitive powers… Alkaloids in plants, especially the hallucinogenic compounds such as psilocybin, dimethyltryptamine (DMT), and harmaline could be chemical factors in the protohuman diet that catalyzed the emergence of human self-reflection." (McKenna, 1995).

It should be noted that toadstool (fly-agaric) has been nominated as a candidate for the plant equivalent of soma/haoma. This point of view was supported by the founder of the new science ethnomycology R. G. Wasson in his well-known book *Soma: Divine Mushroom of Immortality* (1968). However, mushrooms containing psilocybin prove to be much closer to the legendary "drink of immortality" in terms of their psychoactive properties.

Story told by the textile

It is high time to sum up the intriguing story unfolding on the time-worn textile. The men depicted on it, who we suppose to be Indo-Scythians (Saka) or Indo-Parthians, are performing a ritual that indicates that they acknowledge a form of Zoroastrianism - a proof of this is the symbol of Ahura Mazda, the sacred fire altar. The mushroom the king (or the priest) is holding in his hands can be an offering to the fire or it can be sanctified by the fire before it being used to make the sacred drink. The north-western India of that time, where, in all the likelihood, the ritual is taking place, was the meeting place of three ethnos, three cultures - Indian, Iranian, and Greek. Each of them had their own gods: tolerance and worshipping not only of one's own but also of alien gods was a common thing.

To get to the root of the consecration unfolding before us, we should pay attention to such seemingly insignificant details as depictions of bees and butterflies strewn all over the cloth. These insects are the most ancient symbols of worship, and used to have the meaning very different from the present one.



Strewn all over the cloth are the depictions of bees and butterflies. Their presence can symbolize the Other World - the world of souls, the world of ancestors, where warriors get after they have tasted sacred mushrooms.

The essence of these symbols of the living natural world, their mythological meaning can be understood through the words denoting them. A bee, for instance, in ancient times was identified with the Word (the first divine creation) and with the fire (soul). In this connection, the Old English *beo* (bee) can be related to the Indo-European **bh&amacr;-* denoting, on the one hand, "to speak, word," and on the other hand, "burn, fire." In a similar manner, the Persian *eng* (bee) is related with the Aramaic *ogi* (soul) and Indo-European **og-en* (fire) (Makovsky, 1996). The ancient mythology of many peoples is known to identify bees and people (in some aspects). The bee was Arthemid's cult insect; Demeter and Persephone's priestesses were called bees. A bee was the symbol of "honey" Indra, Vishnu, and Krishna. Atharvaveda compares spiritual pursuit with honey-making (Ivanov, Toporov, 1992). The antiseptic properties of honey made it and important means used by many peoples for preserving some foodstuffs. In Mexico, for example, honey has long been used to preserve mushrooms containing psilocybin.

The embroidered cloth covered the narrow space between the burial chamber walls and the coffin. On top of it was a layer of blue clay. Photo by Ye. Bogdanov

In Greek mythology, a butterfly personified Psyche. The Greek word "Psyche" means "soul" and "butterfly." In fine arts, a soul was often depicted as a butterfly either flying out of a funeral fire or going to Hades (Losev, 1992). The meaning "soul" is often related with the meaning "fire, divine fire." In Chinese culture, a butterfly is still an emblem of longevity. The insect's life cycle - caterpillar, cocoon, butterfly - is perceived as a vivid example of metamorphoses leading ultimately to immortality or of a string of rebirths resulting in nirvana (Kravtsova, 2004).

M. V. Moroz, a fine art restorer with the Museum Studies Department of the Institute of Archaeology and Ethnography SB RAS, is engaged in near work: she is removing clay particles from fragments of the cloth.

The butterflies and bees depicted on the background of the canvas may have symbolized the kingdom of souls - the Other World - the world of ancestors, where the warriors got to after having consumed sacred mushrooms.

...Now the puzzle fits together. The insects and the mushroom are closely connected and make the surrounding world miraculous. "We drank soma, we became immortal, we came to the light, we found gods." (Rig-Veda. Mandalas 9 - 10. VIII, 48.3).

The time-worn cloth found on the floor covered with blue clay of the Xiongnu burial chamber and brought back to life by restorers has a long and complicated story. It was made someplace in Syria or Palestine, embroidered, probably, in north-western India and found in Mongolia.

The unique find is reviving thanks to restorers. From left to right: N. P. Sinitsina, a top grade fine art restorer (textiles and leather), head of the Leather Restoration Group with the Department of Non-Conventional Restoration Technologies at the Grabar All-Russian Art, Scientific and Restoration Center (Moscow); Ye. S. Sinitsina, a fine art restorer with the same department; and O. S. Popova, a fabric restorer with the Pushkin State Museum of Fine Arts (Moscow).

Finding it two thousand years later is a pure chance; its amazingly good condition is almost a miracle. How it made its way to the grave of a person it was not meant for will long, if not forever, remain a mystery.

And yet this is not the greatest enigma posed by the unique find. We were lucky to come across something completely new and out-of-the-ordinary. The border of the academic world was stepped across by unexpected evidence, tangible as the textile that has literally returned to us from the other world in order to continue the story about how a man was becoming Man.

Abstract

Evidence is presented to demonstrate extensive use of mushrooms in pre Hispanic Peru. Mushroom images were found on ceramics, metal objects and textiles from a range of important cultures from the north and south, as well as coastal and highland Peru. The objects range in age approximately between 1200-200 BCE to the time of European conquest. Most abundant, vivid images of mushrooms were found from art of the Moche/ Mochica culture, although other in cultures mushroom representations were also clear. Mushrooms, (realistic or abstract) were associated with what appear to be personalities of high authority, to shamans/curanderos and sacrificial victims. Realistic images of mushrooms commonly found associated with shaman like figures were often of high quality and allowed identification of some mushrooms to at least genus level. Identified were Calvatia species, Mochella species, *Amanita muscaria* and *Psilocybe* species. Some mushrooms could not be identified, because current knowledge of mushrooms of Peru and its neighbors is limited. The identified mushrooms have various characteristics: Morchella and Calvatia species have both culinary and medicinal properties. Others, like *Amanita muscaria*, and *Psilocybe* species have spiritual as well as medicinal properties

rather than culinary uses. Since *A. muscaria* has not been confirmed growing in Peru and its traditional hosts are northern hemisphere trees one hypothesis is that the mushroom were a trade item with countries lying further north or Meso America where *A. muscaria* has been shown to have been deeply engrained into the religious cultures. The implications and importance of the findings are discussed for understanding of Peruvian cultures and the ancient mind and history. Various suggestions are made to advance archaeological research by integrating better mycological expertise to improve understanding of these remarkable ancient peoples.

Introduction

Humans have ancient connections to mushrooms. Our ancestors in every inhabited continent on earth used mushrooms. Why? It appears that they were aware of and used the power of mushrooms medicinally, nutritionally and spiritually. Curiously, fungi are probably the most wholesome product that combine nourishment with medicine. They combine high digestable protein, deep mineral and organic essence of the earth with defense and sometimes neurological compounds that are of use to us due to the phylogenic closeness of fungi to us. Mushrooms are in essence a medicinal food tailored to humans.

The oldest known representations of mushrooms have been found in Africa on petrographs from as early 9000 BCE, suggesting that already then they played an important part in human rituals (Samorini G. 1992). The 5000 year old iceman found in Italian alps a few years ago also was carrying mushrooms probably for medicinal reasons, or as fuel. The Romans and Greeks used mushrooms for various purposes including food: Amanita caesarina was a favorite food in Roman times (Phillips R. 1981). Ling-Zhi, Reishi (*Ganoderma lucidus*) is known from 2000 year old Chinese medicinal documents as their most valued medicine, the herb of eternal life (Hobbs C. 1986).

That said, fungi, unlike ancient crops or medicinal plants, have received little attention in archaeological or anthropological studies. The most written about ancient fungi have been those connected with entheogenic species like *Amanita muscaria* and *Psilocybe* species (Schultes 1939, Wasson & Wasson 1957, Borhegyi de 1961, Allegro 1970, Furst 1972, McKenna 1992, Gartz 1995, amongst others.). Wasson & Wasson (1957) believed, the use of entheogenic mushrooms spread over most of Eurasia and the Americas, and as Stone Age Man emerged into the light of proto-history fungi may well have been the primary secret of his sacred mysteries and the development of religion. The reasons for the scarce coverage of the role of fungi in human history maybe the lack of mycological knowledge in archaeological circles, and probably stigma associated with such of research. The result being that in most cases mushrooms in ancient art have been interpreted in almost amusingly erroneous ways (Samorini G. 1992).

In line with the global archaeological and historical trends mushrooms have been rarely mentioned in archaeological literature of Peru. A few authors noted their presence, but their suggestions fell mainly on deaf ears by the academic community (Schultes 1972, Morgan 1995, Borhegyi de 2010). Most notably though, (Poma de Ayala 1615, p. 282-5) a famous indigenous writer in the 'Nueva Cronica y Buen Gobierno' [apparently either using information principally from the remarkable mestizo, legally dead, Jesuit priest Blas Valera, or was his alibi (Hyland 2011)] in passing mentions the significance of mushrooms (Kallampa) in dreams of death in Inca times in the chapter on rituals and ceremonies. He also denotes the month March as the month where mushrooms for food are plentiful in March (p. 1137/8) and notes their importance as food in the Inca diet.

In contrast to the few references in Peru on mushroom use there is substantial mention in the literature of plants and of hallucinogenic plants like Banisteriopsis spp. and species of the genus *Psychotriatha* that produce the DMT containing entheogen 'Ayahuasca", as well as of San Pedro (*Echinopsis pachanoi* syn. *Trichocereus pachanoi*), and of Coca (*Erythroxylum coca* and *Erythroxylum novogranatense*). To illustrate the point, an amazon.com search quotes at least 69 books on Peru and ayahuasca, 70 books on San Pedro and Peru, and of course 468 books on Coca and Peru. In contrast, the www.amazon.com search comes up with nine (9) books on mushrooms and Peru, all are related to modern cooking. The San Pedro cactus is well described in art and objects from the Chavin, Nasca to the Mochica cultures, and Ayahuasca is represented in Chavin art. Coca Is well known from Inca times and the early chroniclers. Morgan (1995) summarized a number of the ancient entheogens in Peru and surrounding countries, including the use of San Pedro and Coca and other commonly used plant based entheogens like those used referred to as vilca, or huila in Peru from the leguminous tree *Anadenannthera colubina* var. *cebil* and *Nicotina rustica* that were commonly used as snuff.

Considering the paucity of information on mushrooms in Ancient Peru, this study aims to begin to illuminate the role of fungi in ancient Andean societies. The objectives of this study are:

1. To document evidence that mushrooms were used in pre Hispanic Peru.
2. To begin to determine which cultures used mushrooms and to establish and make a first estimate of a time line.
3. To determine where possible the likely identity of mushrooms and their use.

It is hoped that this preliminary study will stimulate further interest to better understanding of ancient and indigenous Peruvian people, to revalue the role of mushrooms in society, and stimulate new and further work on this neglected subject, since we now better understand not only the high nutritional and medicinal value but also the crucial ecological role of fungi in the maintenance of life. I apologize from the beginning to colleagues in various fields, particularly in archaeology and anthropology for my inadequate coverage of the impressive amount of literature on history and cultural knowledge of Peru. In not doing so I have left much of their work unacknowledged. However, I believe that it is important to bring out the information on mushrooms in ancient Peru earlier rather than later for it to be available in the overall efforts to better understand the history and use of its biological diversity of this remarkable country that has played a central role in the history of humanity.

Materials and Methods

Materials

For the analysis ceramics, textiles and stone work were visually examined for mushroom representations The base materials were derived mainly from the Museo Larco, Lima, who kindly provided me with access to their full online collection. Other material was obtained from various museums in Peru and around the world and the internet. Other material was collected directly in the field by the author. Sources of information are acknowledged when used.

Identification of mushrooms

To identify mushrooms the shape, color, representational details of ancient artists, as well as the relative size to the known usually human features were observed. These were compared with known mushrooms from Peru, and the world, using various sources. A major limitation with identification of the mushrooms was the limited documentation of mushrooms in Peru. Major identification sources were (Pavlich 1976, Arora 1986, Stamets 1996, Pavlich 2001, Wright & Albertó 2002, Mata *et al*. 2006, Holgado *et al*. 2007 and collections in 2001 and 2012 see www.globalmountainaction.org)

Results and preliminary discussion

Mushrooms in Ancient Peruvian Cultures

The first step in evaluating the importance of mushrooms was to document their use through time by different cultures. In the past Peru had many cultures that flourished and disappeared. We know of most only through archaeological evidence and names retrieved through folklore, or attributed to them by those studying them, since no form of pre-conquest writing is yet known to have existed or has survived. The findings that follow result from a limited survey of ceramics, textiles and other art and are not meant to be exhaustive, but rather preliminary. The purpose of this section is to demonstrate the presence of mushrooms in various cultures over time.

Coastal Cultures

Cupisnique Culture (1200-200 BCE)

Cupisnique culture on the north coast existed from around 1200-200 BCE and declined at a time when the Moche or Mochica culture was gaining in strength. A beaker in the Metropolitan Museum (Fig. 1), depicts a mushroom tree, probably a tree of life. The mushrooms are being shown in cross section. Initial finds at the recently found Cupisnique Callud temple, around Lambyeque also show themes associated often associated with mushooms in other cultures, such as feline images and decapitated heads (Orozco 2008), although the connection, if any, with a spider deity is unclear. The presence of mushrooms in Cupisnique culture suggests mushrooms in Peru were known and used as long as in the oldest Meso-American societies, like the Olmec, who have been shown to have used mushrooms.

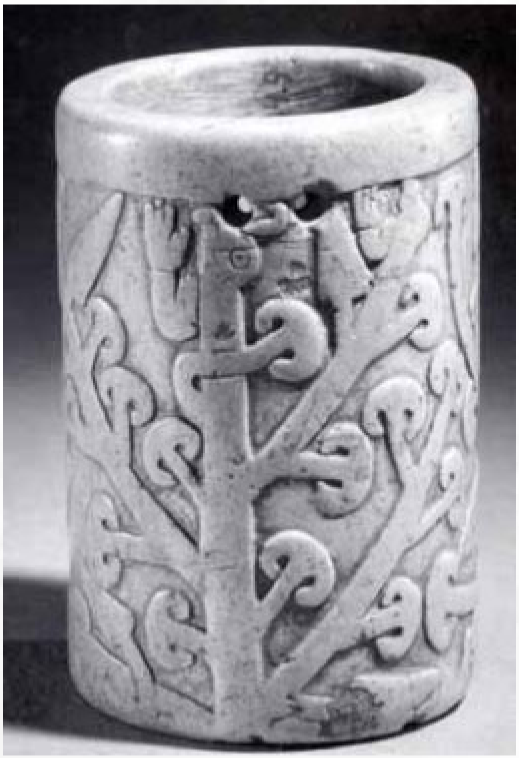

Figure 1. Cupisnique mushroom beaker.

Paracas Culture (800-100 BCE)

Paracas culture prominently features mushrooms in its textiles and ceramics. Some may be taken for Tumi's (mushroom shaped ritual knives) and perhaps the duality was an intended part of the symbolism. In other cases it is clear the images represented are mushrooms. The textiles in figures 2 (a and d) show shamanic beings in flight with a mushroom shaped structures in either one or both hands (an unlikely tumi scenario). Flight was a shamanic ability brought about by the use of entheogens, which here may be represented by the yellow mushrooms. The 'google' eyed image in figure 2b holds two yellow capped mushrooms on a staff like structure in the right hand (also an unlikely Tumi scenario). On the head there also appers a mushroom like image. The ceramics in figure 2c, show a spider like creature in a trance holding a conical capped structure and one on its head, characteristic of *Psilocybe* mushrooms. The representation of mushrooms in the Paracas culture may indicate their role in the transformation, since through transformations it is believed shamans were able to communicate and even battle with spirits and thus heal illnesses or become clairvoyant.

The Moche (Mochica) culture (100 BCE-800 EC)

The Moche, a well known culture for its ceramics and spectacular archaeological finds ((Bawden G. 1999), (Quilter J. 2011)), produced ceramics with unmistakable representations of mushrooms. As a society they share many similarities with the Tumaco-La Tolita and Valdivia culture of Ecuador and Colombia (Errázuriz J. 1980). They provide the most expressive, varied and the most clear evidence of all the Peruvian cultures that mushrooms were used and played an important part in ancient Peru. They developed highly realistic representations of people and daily life. As such, Moche art provides a window into the minds and rituals of its people unequaled in other culture. Through it, there is a unique chance to better understand the role of mushrooms in the ancient Peruvian world.

To begin, there appear to be three different forms of mushroom representations in Moche society. The first, there are unmistakable, large realistic representations of mushrooms (Fig. 3). The second, subtle 'hidden' representations of mushrooms that are easily missed if one is not looking for them, but clear when one has found them. The third form is an abstract symbolic or iconographic representation of mushrooms or uses with which they were associated. Only, the direct representations will be discussed here.

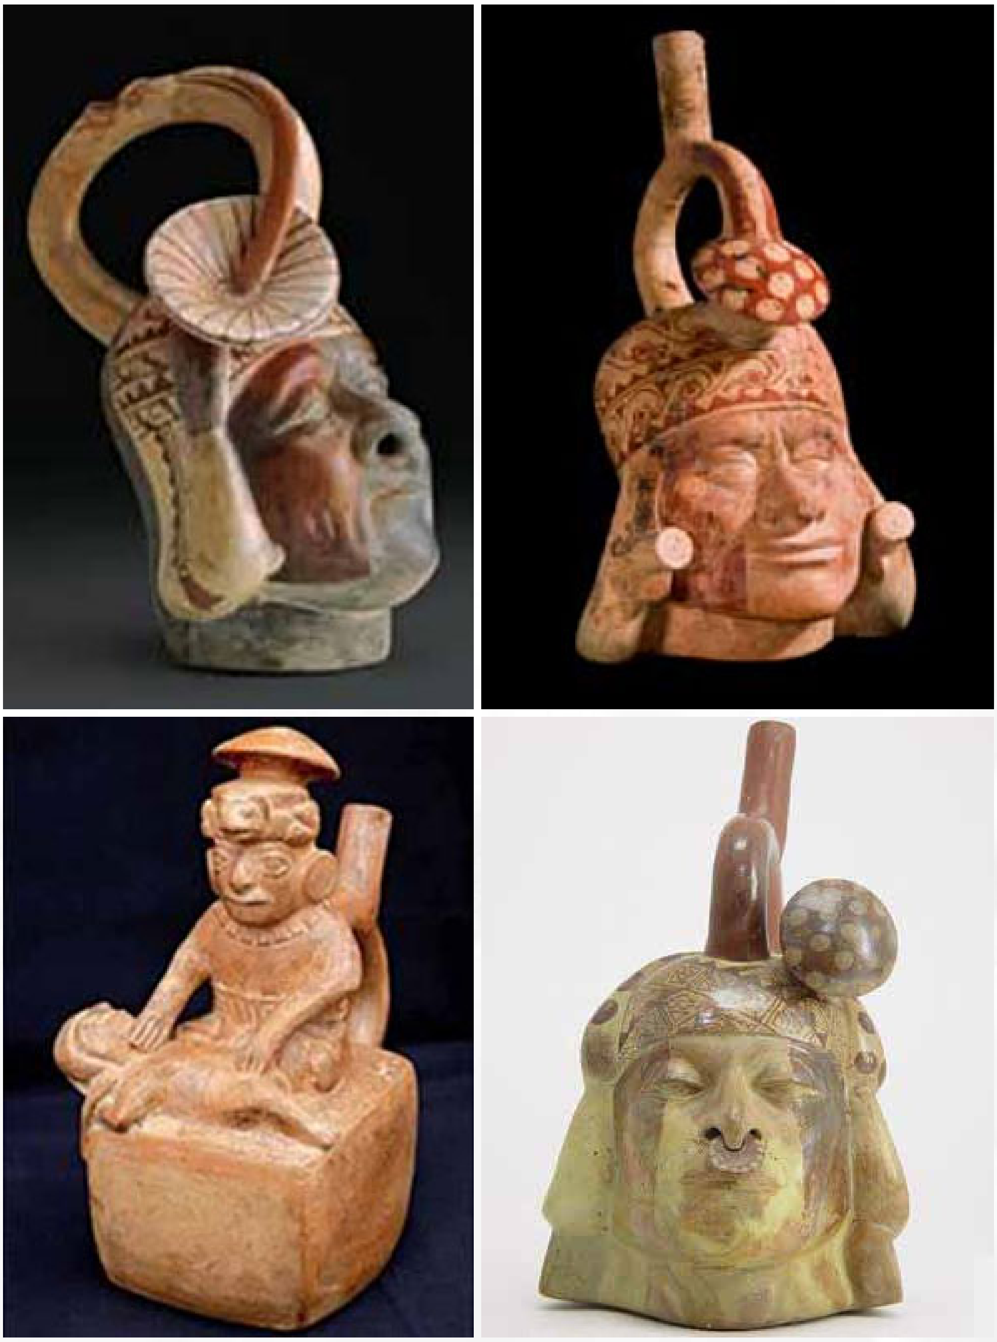

Figure 3. Moche ceramic figures with mushrooms protruding from their heads, represnting medical and perhaps spiritual use of mushrooms.
Sources: a. Borhegyi 2010, b) Peabody Museum 16-62-30/F729 c. Symbol of the Foro Medicina Traditional Peru. d) Museo Larco ML000136

The Moche represented mushrooms clearly enough to enable us to begin to identify some of the species at least to Genus level and thus begin to relate them to current knowledge about the fungi associated with the Moche.

Each of the highly realistic, individualized busts of Moche personalities is loaded with iconography and symbols inclduing mushrooms. The images (in figure 3) have unmistakable mushrooms either on top, or on the side of the head, and figure 4d has both. The image (Fig.3 a) has a mushroom growing over his head, with the gills and mycological characteistics of the mushrooms clearly shown. The mushroom appears to have free, light gills that are termial split or at least appear split to an observer. The stipe is brown and has no annulus. The presise nature images is presented alone demonstrates profound knowledge of the Moche of mushrooms. The image on the lower left (Fig. 3 c) is clearly what would today be called a curandero. The individual is kneeling above a child who is evidently ill. On his head there is a prominent mushroom. It is an example of medicinal use of mushrooms in ancient Peru. The image on the top right (Fig. 3 b) has a umistakable red capped mushroom with white dots. The examples carry mushrooms known for food, medicine as well as religious use. (For more detail see the identification section). They demonstrate that the Moche had various uses for mushrooms. It should be interesting to check mushroom definitions in early dictionaries of the now extinct Moche language.

The extent to which mushrooms are represented in Moche society, especially from ceramics from particular areas such as the Virú valley suggests mushrooms may have been more important in some places than others. Moche images will be presented in various sections of this paper to demonstrate associations of mushrooms in ancient Moche and some Peruvian society.

The Chimú culture (900-1470 CE)

The Chimú culture became dominant in northern Peru after the decline of the Moche societies with whom it was linguistically and culturally closely associated. The culture lasted until they were integrated into the Inca Empire around 1462-1470 AD. There is clear evidence of mushroom representations in Chimú art and thus of the continuation of mushroom knowledge from one time period to the next. On the bottom left (Fig. 4), we see a Chimú textile with a figure (Schindler 2000). On his head a we see a mushroom like crescent, not unlike that seen in important personalities of Moche societies, and perhaps symbolic of spiritual and earthly power. The stipe of the mushroom is unlike a typical tumi, it is shaped with what looks like a volva typical of *Amanita* species. We see a similar image in Borhegyi (2010) where the Chimu image is standing above a mushroom (without volva) growing from the ground. On the botom right (Fig. 5) we see a textile of a priestlike figure also holding a mushroom with volva in his right hand with a mushroom cap whose spots are reminicent of the genus Amanita.

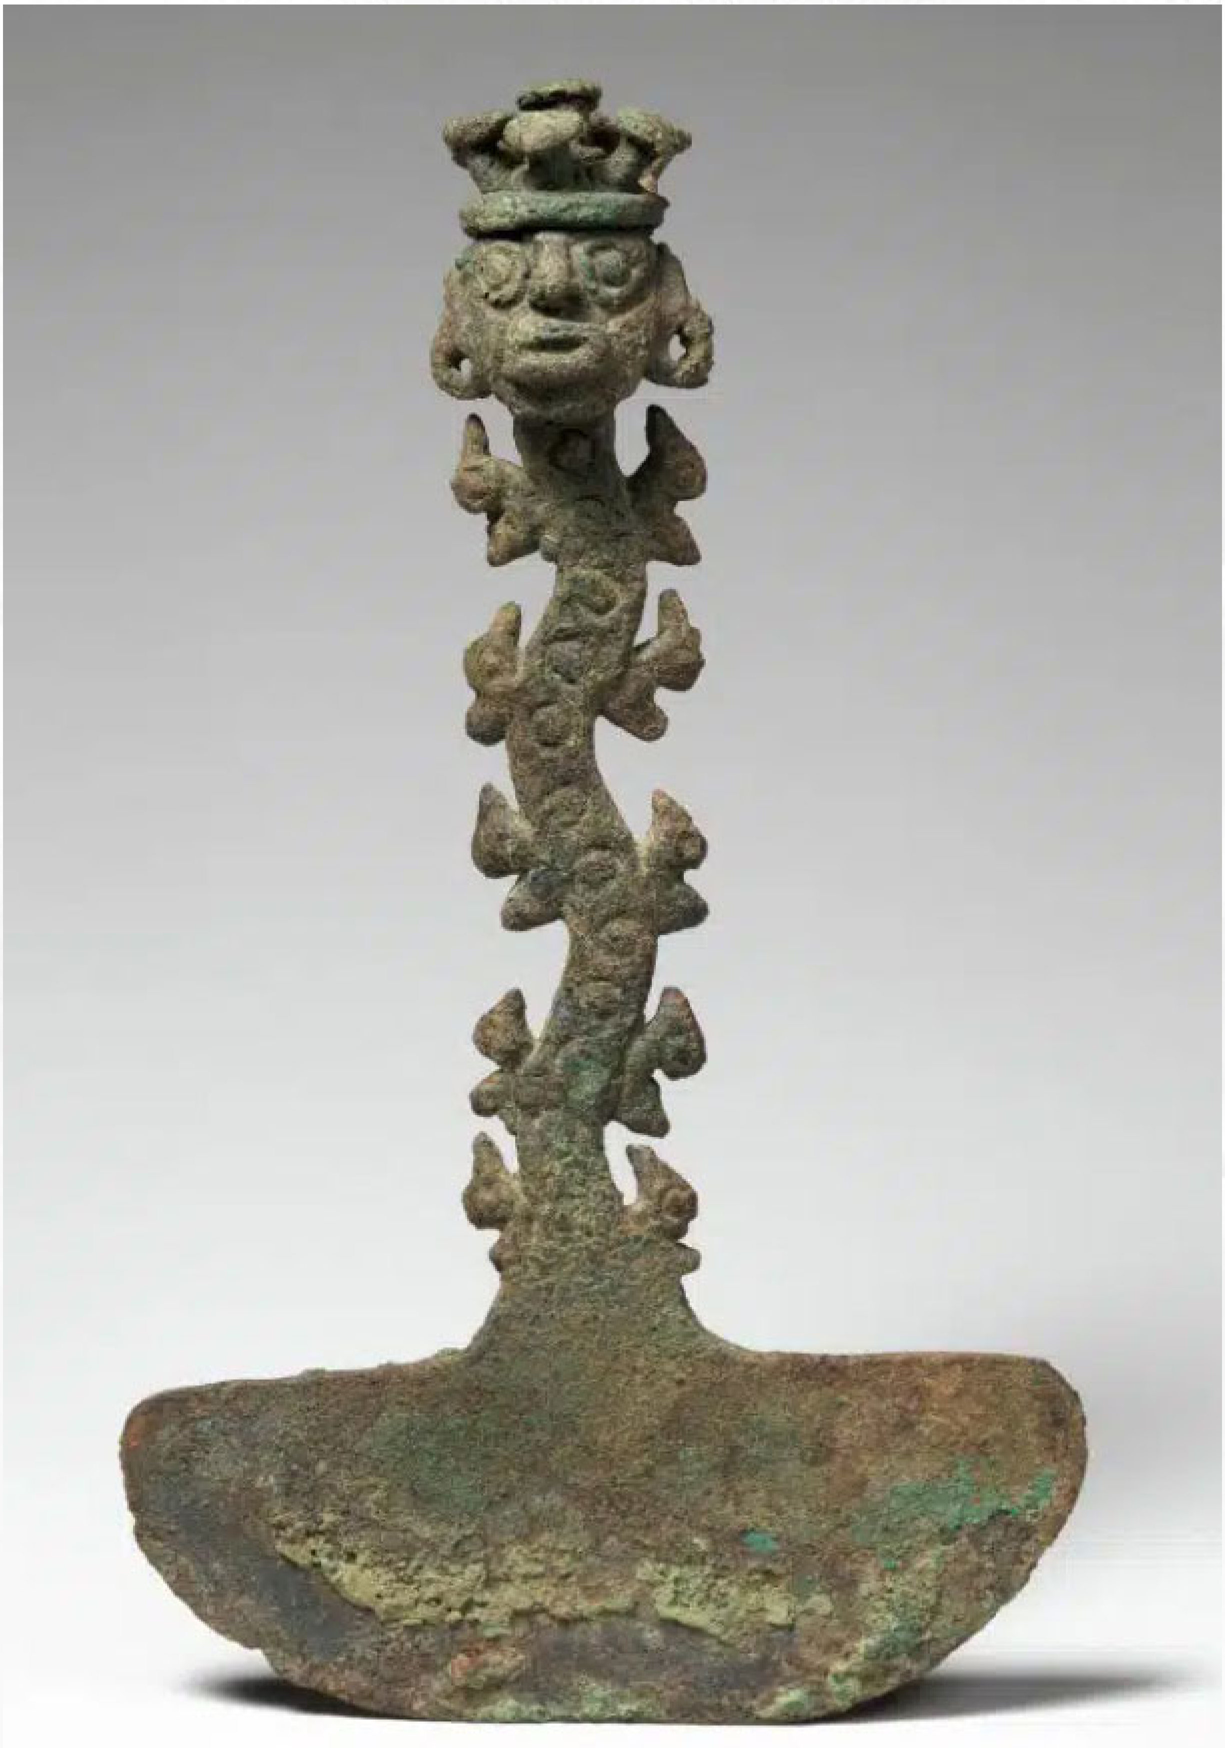

Figure 6. Chimú tumi with mushrooms.
Source: Metropolitan Museum Number: 1987.394.216

On the top right (Fig. 6) there is an example of the association of mushrooms with Tumis in Chimu society. The tumi, a religious sacrificial knife, not only is mushroom shaped by has a long neck with birds and a head out of which mushrooms are growing.

Highland Cultures

Pukará Culture (1200 BCE - 400 CE)

The Pucará culture was of profound formative importance in the region for the Tiahuanaco and Wari cultures that succeeded it. Some indigenous groups like the Callawaya still speak a language based on a mixture of Ayamara and Pucará. The Pucará site built under a rock formation with looks like a feline, probably a puma.

Few Pucará ceramics have been evaluated to date, however there is strong visual evidence that mushrooms were used ritually. In figure 7a, a ceramic feline representation of the Pucará culture has red mushroom cap shaped ears attached to a what appeat to be mushroom stipes of slightly darker color. The feline has 'google' eyes, suggesting a trance state. This image can be found repeated in numerous similar ceramics. It is a curiously similar design to that found of the Wari culture where the anthromorphic feline, has undisputable mushrooms instead of ears (see Figure 11).

The Pucará culture also produced mushroom shaped stones (Fig. 7 b). Their caps appear more like young mushrooms, but with clear deliniations of stipe and cap. They may also have phalic symbolism, but lack an orifice as well as a realistic phalic head shape suggests the principle intent was to represent a mushroom. Certainly they are not just wights (pesas) as indicated in the museum.

The 'Mushroom stones' of Chucuito, Lake Titicaca

On the North west side of lake Titicaca, in the town of Chucuito, there are stones, finely carved from volcanic and other rock, in the shape of mushrooms (Figs. 8 & 9). The age of the stones is not known. They may be from Inca times or earlier. The Chucuito mushroom stones, although less elaborate, have similarity to those found in Mexico and Guatemala (Borhegyi, 1961) whose original purpose also is not yet known.

The pre-columbian temple, which now houses the stones, was studied and verified as an Inca structure in 1950 by Harry & Marion Tschopik (Kummer L.J. 2006). However, it appears no serious studies have yet been conducted to better understand the context of these stones. The stones bear little resemblance to sculptures at Tiahuanaco on the other side of lake Titicaca, but do have striking similarity to the mushroom stones of the Pucará culture in the north (Fig. 7 b). Some of the sculptures may have some similarity to Inca stonework, although no Inca mushrooms sculptures appear to have been found at other sites. For the purpose of this study the culture will be referred to as the Chucuito Culture, a culture which appears to have had connection to the Pucara and Inca cultures.

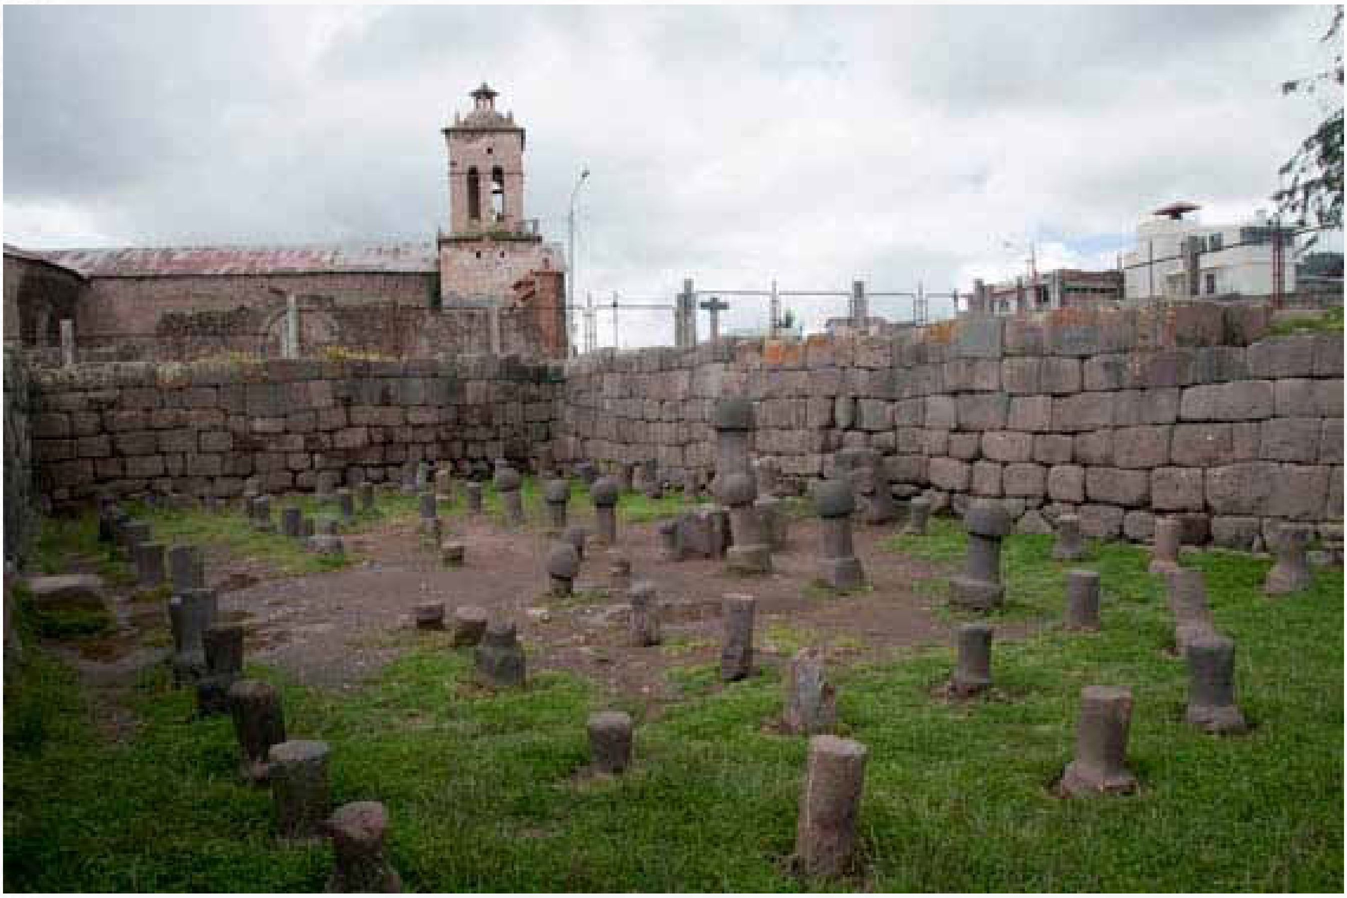

Figure 8. Inka Uyo, with the collection of mushroom and ordinary roof bearing stones found in and around Chucuito Source: Peter Trutmann©2011

The origin and purpose of the mushroom stones remains a mystery. There has been an unfortunate confusion created by a decision by the town in the 1970s to bring together in the genuine late Inka temple structure called Inka Uyo, all mushroom stones found in and around Chucuito to create a tourist attraction as a temple of fertility for which it is now famous (Figure 8). In a New Times article Kummer (Kummer 2006) questions the authenticity of the temple of fertility, and whether the stones truly represent phallic stones. Incredibly, neither he nor the anthropologists he consulted touched the possibility of the stones representing mushrooms, or their deeper symbolism. One Peruvian archaeologist considered the mushroom stones to be roof beam baring stones of Inca buildings (ibid). It is true that of the over seventy stone structures at the temple only 14 are mushroom shaped. The rest are classic Inka roof baring stones (Fig. 10 a). These are straight stone cylinders on a square base that were implanted into the wall of the buildings like those common of Inca structures found in other parts of Peru (10c). Of the mushroom stones, those with clear caps (Fig. 9), only one has clear dual phallic features (Fig. 9 c). Its dimensions much larger than the other mushroom stones. It is the only one with an apical cleft.

Over half of the mushroom shaped stones in the temple could also have functioned as roof baring stones with special mushroom symbolism (Fig. 9 b). Although these mushroom stones are more finely worked, they have shafts of similar length that could have carried beams. They also have a base similar to the ordinary roof baring stones that could have been lodged within a stone wall (Fig. 10 a,b,c). They are all almost identical in form, suggesting they were manufactured for the same structure or official use. Perhaps, they were used to decorate the top of a temple that used mushroom or their symbolism? That symbolism may have included fertility.

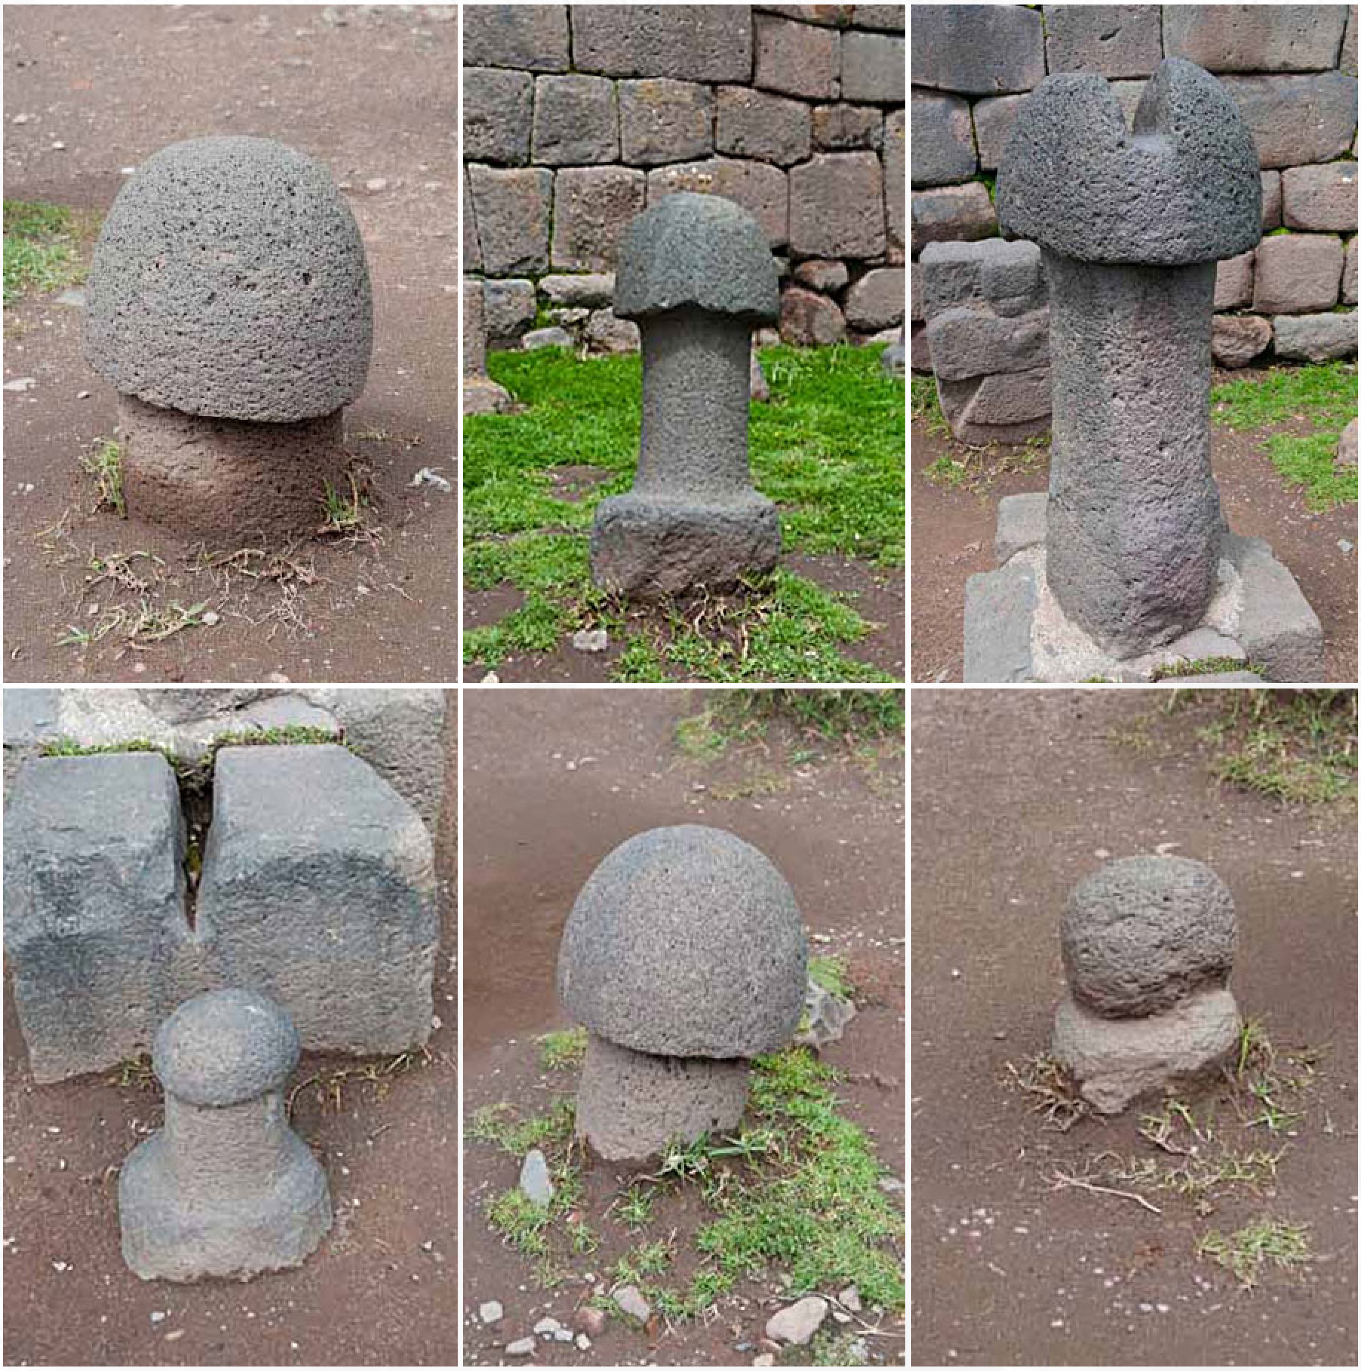

Figure 9. a-f. Mushroom shaped stones with stipe of various lengths and clearly defined caps. 9f. Dually symbolic mushroom/ phalus stone with apical orifice but cear mushroom cap, rather tham phalus head shape. The orifus could also represent the entrance to the underworld as could the v shaped stone in 9d.

The other mushroom stones found in Chucuito have shafts of shorter lengths (Fig. 9 c-e). These shafts are so short they would never have been useful to secure a roof beam. or so large (as in the case of the phallic mushroom stone shaft and cap measure 1.2 m) that it is unlikely that its original use was to bear beams. It suggests that these mushrooms were intended to be placed on the ground.

Using the findings, there is a strong case that in ancient times around ancient Chucuito mushrooms were considered with sufficient reverence to carve stones and images of them. The mushrooms fit into evidence of pan Peruvian use in pre Hispanic times. Although we cannot yet identify the mushrooms represented at chucuito with certaintly for lack of mycological knowledge of the region, or know their exact use, it is likely that one association was associated with fertility and/or feline transformaton related rituals, since Chucuito also is associated with the Puma.

Wari culture (500 to 1000 CE)

The Wari (or Huari) Culture was a highland culture, which dominated most of present day Peru. It accupied Pacacamac, a major religous site and Andean mecca, although it retained much autonomy, and took over much of the territory formally occupied by the Moche. They are believed to have made major technolgical and organizaitonal breakthroughs such as development of an extensive road structure as well as the use of terracing for Agriculture.

The Wari culture also incoporated elements of earlier Tiahuanacu culture, including representations of the personalities of the gate of the sun in Tiahuanaco, as well as elements of Nasca style art. The ceramics often depict realistic, rather than abstract, images with symbolism, much like the Moche societies, that enable easy identification of mushrooms. For example, the vase below (Fig. 11 a) contains a painted anthro-morphic image reminiscent of the Pucará puma with fungal structures reminiscent of Pucará ceramics. The feline fungal ears differ inthat those of Pucará represent mushroom caps, whereas those of the vase are the form of puffballs.

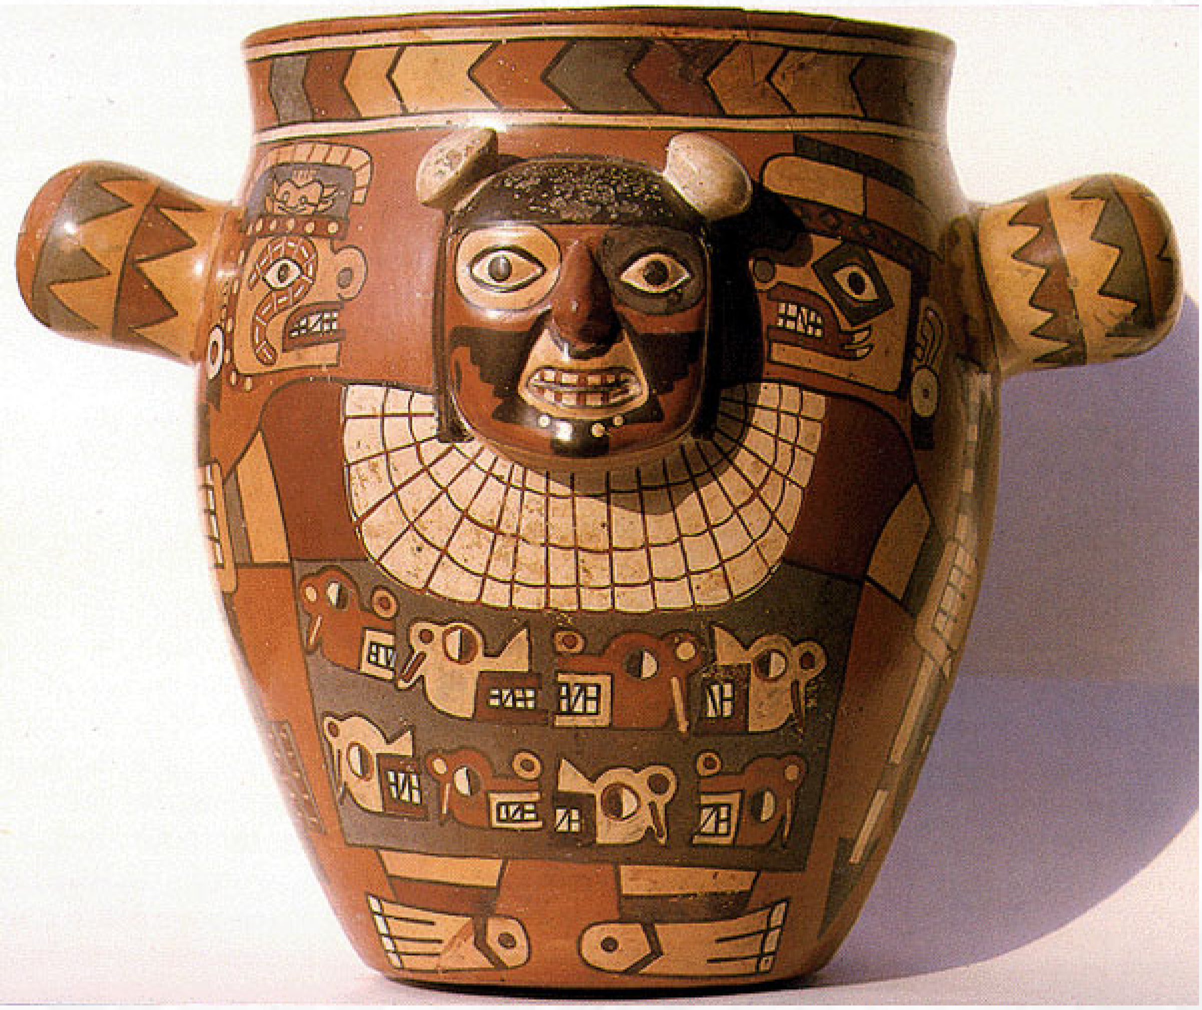

Figure 11. a) Anthromorphic image with puffball mushroom ears Source: Caceres j. 2004.

Mushrooms and the Incas (1200 - 1532 AD)

Little material was studied from the Inca period. Nevertheless, considering that the Chimu culture connected chronologically directly to both the Moche, Wari and to the Inca cultures, it is very probable the Incas knew of mushrooms. The Inca were known to incorporate other religions and worship into their own as seen in Pachacamac and other sites of conquered peoples. Certainly, we know from Poma de Ayala (Poma de Ayala F.G. 1615) that in Inca times mushrooms were part of the indigenous diet. Furthermore, Inca mythology and language is highly suggestive of an association with mushrooms (Delgado Diaz del Olmo 1996).

There are pieces from the Machu Pichu collection returned by Yale and now housed in the Museo Machupichu that show the Incas produced images of mushrooms in gold (Fig. 12). The pendant contains an cross-sectional image of a convex to broadly parabolic mushroom cap, the shape of some neotrophic mushrooms. There are also mushroom shaped earplugs. From what remains of the color, they were clearly painted red with what faintly appears like white dots. Coming from Machu Pichu, a sacred site, it would not be far fetched to suggest that sacred mushrooms may have been part of ritual life and symbolism in such a richly forested region filled with some of the greatest biodiversity in the world?

Cultures of the Selva and Amazon Basin

Information about pre-Hispanic mushroom use in the Selva and Amazon basin is limited. Gartz (1996) mentions:

> *"Jesuits of the 17th and early 18th centuries who had traveled to the western Amazon (Peru) reported that the Yurimagua Indians habitually prepared a potently intoxicating potion derived from a tree-dwelling mushroom. The mushrooms appeared on fallen trees as a kind of reddish growth with a spicy taste. The potion was said to be so potent that nobody who swallowed three mouthfuls of the brew was able to resist its effects. The mushroom was considered to be Psilocybe yungensis Singer & Smith. However, since Gymnopilus species are reddish in color .... and tend to colonize dense tree trunks, those strange tree-dwelling mushrooms were most likely a Gymnopilus species".*

There are few studies of current mushroom diversity in the Peruvian Amazon. The most complete study document substantial diversity of mushrooms including consumption of over 30 species for food by indigenous groups (Prance 1984, Door & Abad 1990, Espinoza 2003, Mata *et al*. 2006). Ethno-mycological reports of sacred mushroom use by Amazonian groups near Peru were made by Schultes and Reichel-Dolmatoff (Davis 1997). Although *Psilocybe cubensis* and other *Psilocybe* species have been reported from the Peruvian Selva (Pavlich 1976, Guzmán 2009), there is no ethno-mycological association as yet with these fungi. Mushroom use is known by present day shamans practicing ayahuasca rituals from the Pucalpa and Iquitos regions. They do not use mushrooms, but know about them. Their belief is that mushrooms are from down below, associated with the underworld, and prefer to leave them alone. (Trutmann 2009).

It is clear from these studies that in the Amazon basin some indigenous groups used mushrooms in religious rites and today still use substantial diversity of mushrooms for food and for religious rites. Perhaps these groups will be able to provide insights into their significance and use by ancient Peruvian societies.

Identification of mushroom species

One of the Mushrooms found represented clearly in Moche (Fig. 13 b) and Chimu societies (Fig. 5), containing volva, a red cap and/or with dots undoubtedly are representations of the famous *Amanita muscaria* (Fig. 13 a). It may be represented in more abstract terms in the art of other cultures such as the Paracas, and Incas. Some scholars believe *A. muscaria* to have been associated with humanity since formative period of religion by ancient peoples from Europe to Asia in the old world and Meso America of in the new world (Wasson 1972). In his writings Wasson provides evidence to suggest that the 'Soma' of the Indo-Europeans was in fact *A. muscaria*. Borhegyi (2010) describes its use in Mesoamerica. It has to date never been reported as used in ancient Peru.

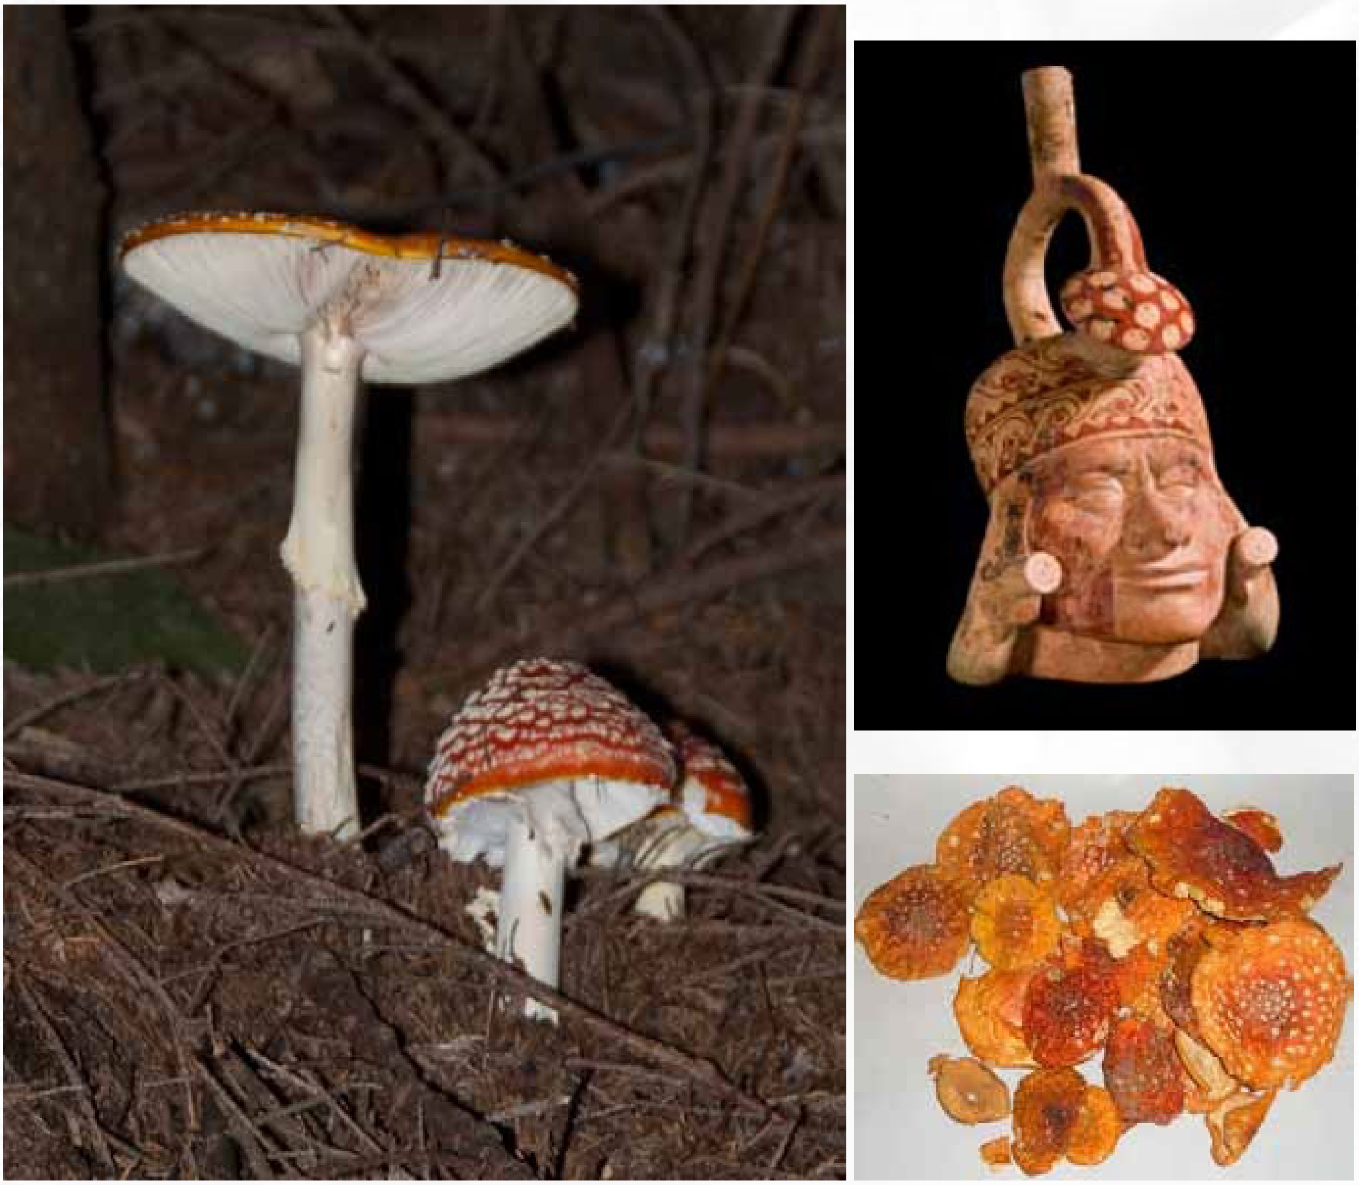

Figure: 13. a) *Amanita muscaria* mushroom. b) Moche figure with *A. muscaria* mushroom c) Dried *A. muscaria*
Sources: a) PeterTrutmann©2011 b) Peabody Museum 16-62-30/F729

The Amanita enigma

Amanita muscaria, belongs to the genus Amanita, a group of white spored basidiomycetes with a universal veil that covers the young fruiting structure.*A. muscaria* is characterized by red caps with white dots that are remnants of the torn universal veil. The stipes (stems) have a bulbous base called a volva and an annulus or ring. is an ecomycorrhizal fungus that forms symbiotic relationships with a wide variety of trees, including pine, spruce, fir, birch, and oak that are principally northern hemisphere trees. Only oaks have as southern limit the northernmost part of the Peruvian Selva (Bush & Flenley 2007). From this perspective it is not surprising that *A. muscaria* has in modern times not been recorded in Peru. How then can it be that *A. muscaria* representations were found in Moche figures that are more than a thousand years old? The first possibility is that it has to date not been carefully and extensively looked for in Peru. This remains a likely possibility, since as mentioned, Peru remains relatively unexplored from a mycological perspective. it may be found in the most northern part of Peru to which northern cultures would likelyhave had access. There is also a the possibility that A muscaria uses other tree hosts in Peru. Many Amanitas in South America from southern Brazil northward and east of the Andes are symbionts of leguminous or polygonaceous plants and few Amanitas of the region (as well as many in the continent's southern "cone") may not require a mycorrhizal partner (Tulloss R. 2006). Information from Australia, a southern hemisphere country, indicates that *A. muscaria* is able to form new associations with southern beech and now is considered as a weed. It is also invading native rainforest in Australia, where it may be displacing native species. There are also reports of its association with Eucalyptus in Portugal. Thus, it is likely that in ancient times *A. muscaria* had already adapted to other host trees common to the Andes in areas where its normal hosts no longer grew.

The other option could be that *A. muscaria* used by Peruvians did not originate from Peru but was imported. Since trade is known to have been extensive in pre conquest times, it may be that dried *A. muscaria* was a prized trade item with northern lying countries, especially in Central America. Dried mushrooms would appear a perfect trade commodity due to their light weight and probably high commercial value (Fig. 13 c). Curiously, it is also in the dried form that *A. muscaria* was most commonly used in many cultures, because as such it had a higher potency and had less gastrointestinal toxicity particularly if parboiled. It is noteworthy that Wasson *et al*. (1986 p. 48) quoting work of Robert Laughlin of the Smithsonian with Tzotzil speaking Mayas in Chiapas, who use the term for *A. muscaria*, 'tzajal yuy chauk' meaning red thunderbolt's yuyo. The fly agaric is still called the 'yuyo de raya', a latinized version. Astoundingly, the origin of the word 'Yuyo' appears to be Quechua. How would such a word have entered into the Mayan language? If true, there must have been substantial contact between the peoples pre Hispanic times probably up to the Spanish conquest. The word 'yuyo', which today in Quechua has meanings such as 'wild herb' must have been used intensely enough to have displaced a local word in the local vocabulary, where it stayed as a reminder. Without (or with little) native *A. muscaria* frequent trips from the Peruvian coast, where large trading rafts were documented at the time of first arrival of the Spaniards, could have shipped this highly valued item from Meso American shores where *A. muscaria* grew and people knew how to prepare them for use probably by the Peruvian elite who might have controlled its use.

It will be a challenge to prove the origin of ancient *A. muscaria* in Peru, whether it was a trade item or whether it was collected locally. If the mushroom is found in Peru it may have been introduced with northern host trees, like pines, since the European invasion. Molecular genetic studies will be required to compare isolates with known isolates from across the world to provide information on similarity. The best avenue to start might be to search for fungal residues in ancient ceramics. If *A. muscaria* spores were to be found comparison could be made of the ancient DNA with known strains since molecular studies of the taxonomic status have been conducted (Geml *et al*. 2008). *Amanita* from Chiapas or Guatemalan highlands or other places in the world should at have a different DNA fingerprint to a native Peruvian *A. muscaria*.

Calvatia and other Lycoperdon based Puffball species

Mochica and Wari ceramics often have globular, or semi globular, structures with or without some element of a base that are broader at top than base (14 a,b), and with or without spots on the upper surface (Fig. 14 a,b) The colors are range from white to dark brown. These structures growing out of heads have in the past often been classified as war-clubs (pora). To mycologists these structures, like other mushrooms already described, are clearly fungal. At first glance contenders look like either young fly agaric specimens, or Puffballs of the

Order Lycoperdon. *A. muscaria* can be ruled out due to the white to brown, rather than red, representation *A. muscaria* (See Fig. 13 b), and the inverse conical nature of their stem like structures rather than more or less cylindrical stipes with caps.

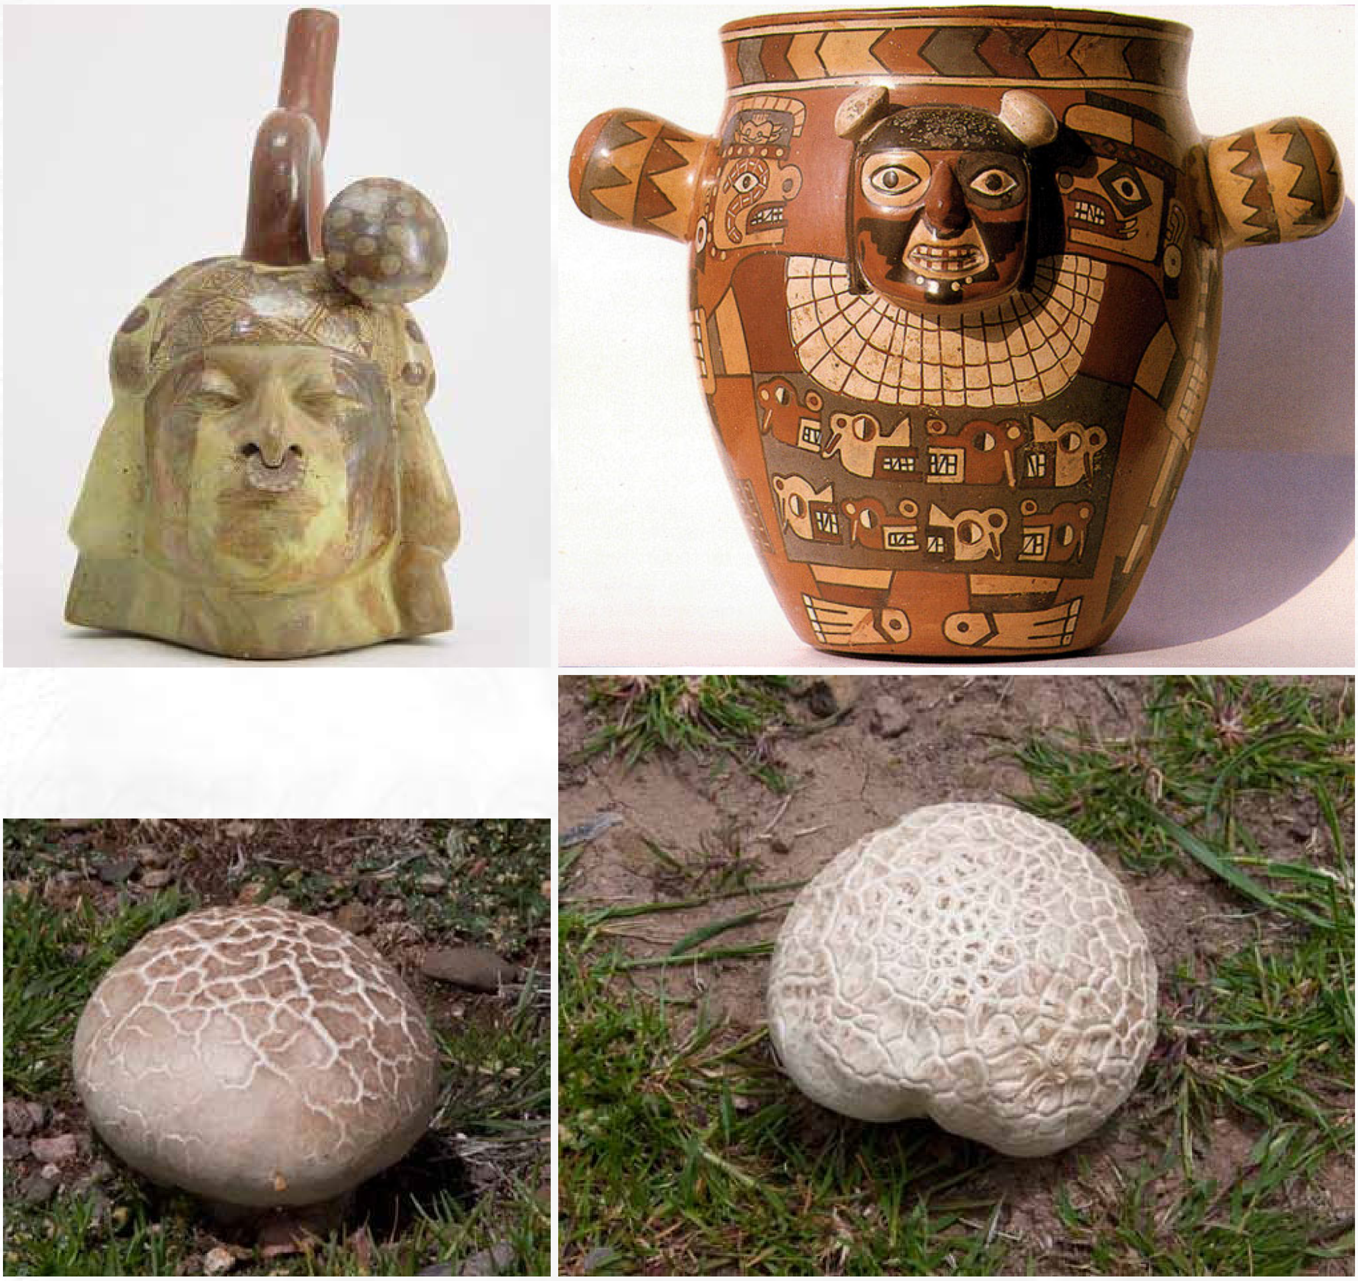

Figure 14. a) Moche shaman or '*curandero*' with *Calvatia cynthiformis* affin. on head b) Wari bowl with anthomorphic figure with young Cavatia species probably *C. cynthiformis* ears.
Sources: a) Museo Larco, Lima b) Caceras J. 2004. c) *Calvatia cynthiformis* mature d) *Calvatia cynthiformis* imature. Photos: c & d PeterTrutmann©2011.

The candidates that best fits the description of both coloration, overall shape and basal attachment are members of the large puffball genus, Calvatia. Various Calvaria species grow in the Andes and may have been used. *Calvatia cyathiformis* and related species, are the most likely candidates (Pavlich M.R. 1976). since they are commonly found in the savannas of the Andes. Its outer peridium or skin is either smooth, as in white specimens (Fig. 14 d), or warty as in darker, older specimens (Fig. 14 c), showing a distinct mosaic pattern that resembles the dots on the Moche structures (Fig. 14 a,c). The short stalk like sterile base is thin at the bottom and broad at the top similar to ceramic representations.

We are only beginning to discover the traditional uses of *C. cyathiformis* and related species in Peru. Calvatia is consumed by local especially Quechua speaking people when young and tastes like cheese. It has high in protein value reportedly of the order of 50%. Calvatia species have found widespread use in the folk medicines of various cultures, especially as a haemostatic (styptic) to stop bleeding and wound dressing (Baker 1989).

With this in mind, could it be that it as used as such in pre Hispanic times as such in Peru? Some Moche images suggest that they may have been used to stop bleeding (scarring) of wounds. For example, figure 15 shows a warrior with a Calvatia like fungi strapped to his head. Courl it have been used as a battle wound dressing? In the figure *C. rubrotincta*, a redish Calvatia, might be represented. Although it has not yet been recorded in Peru it is characterized by red spots when young and is very similar to *C. cythiformis* (Arora 1986 p.687). Could it be the Moche were representing in these ceramics persons injured in warfare with the dressing of wounds? In the Andes of Argentina *C. cyathiformis* is known as "polvillo del diablo" and still used for the scarring of wounds (Martínez and Luján 2011).

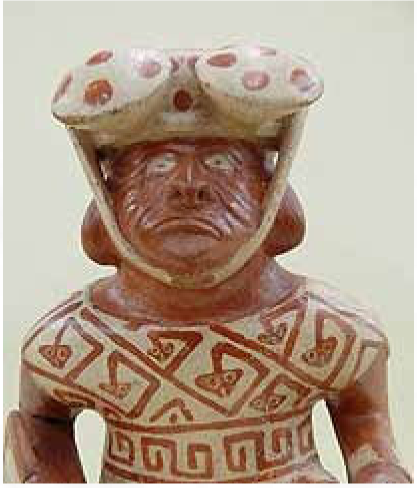

Figure 15. Moche warior with two Calvaria species with red dots on head.

Calvatia has been used to treat a variety of other ailments such as leucorrhoea, pneumaturia, Inflammation, diarrhea in calves, etc. and has anti-cancer properties (Coetzee and van Wyk 2009). *C. cyathiformis* and other puffballs may also have had use in spiritual rituals. Evidence for this comes from Colombia. ReichelDolmatoff, the renowned anthropologist archaeologist described the use of a blue puffball in ritual use of psychoactive mushrooms among the Kogi, the descendents of the Tairona (Reichel Dolmatoff 1977 p. 285). *C. cyathiformis* is known to have purple spores when aged, and can turn bluish. It may be the fungus described by Reichel Dolmatof.

Psilocybe species

There is clear evidence that *Psilocybe* species were used by the Moche and other societies like the Paracas where conical shaped mushrooms were represented in textiles. Below a Moche shaman or priest is shown with a head dress that look remarkably like young *Psilocybe* species (Fig. 16) similar to *Psilocybe semilaceata* or even *Psilocybe cubensis* (Fig. 17). Many other Peruvian examples of mushrooms with curled cap cross-sections such as those of the Cupisnique and Inca cultures are likely also to represent *Psilocybe* species since it is a characteristic of various and have been used as such in Mesoamerican cultures (Borhegyi 2010). Even in Inca mythology there association of golden conical caps and lightning, with the origin myths and the founding of Cusco (Delgado Diaz del Olmo 1996).

To date only a few *Psilocybe* species have been reported in Peru (Pavlich M.R. 1976, Guzmán *et al*. 2000, Guzmán G. 2009). These include *P. cubensis*, *P. yungensis* and *P. zapotecorum*. *P. cubensis* is thought to have been introduced later after the European conquest with livestock that reached the Andes through the Caribbean. However, this is but speculation. It is just as likely that the species represented in the ceramic was already present in Peru though the movement of populations, Andean livestock and trade. If so it may well have been *P. cubensis* that was represented in the ceramic.

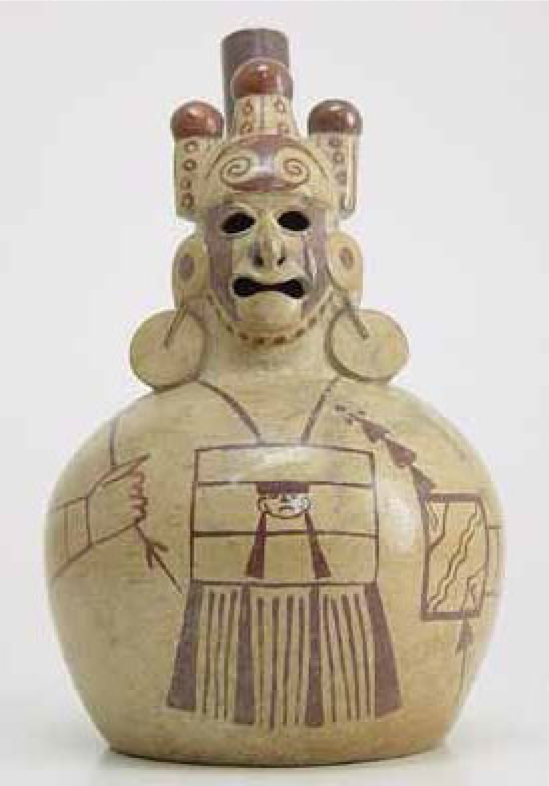

Figure 16. Moche personality with young *Psilocybe* featured on the back of his head. Source: Museo Larco, Lima

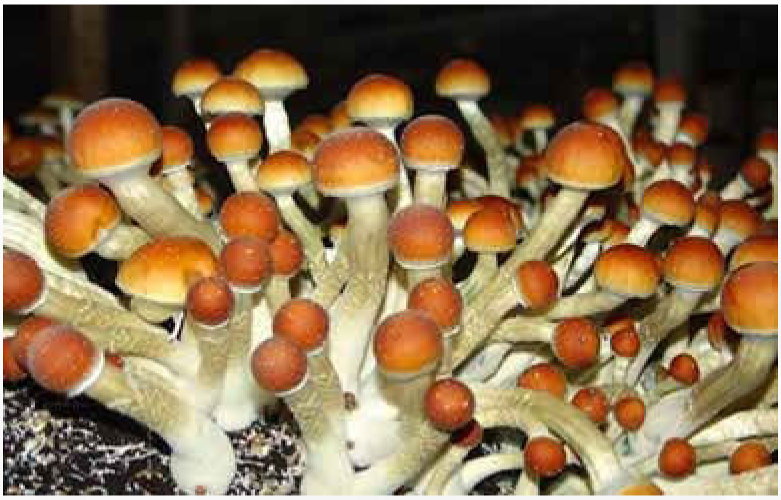

Figure 17. Young *Psilocybe cubensis*.

Psilocybe species were used as an entheogen in Meso America, and documented in Mayan and surviving Aztec texts such as the *Popol Vuh*. In the middle of the last century their use was rediscovered. Wasson brought these rituals to the attention of the world (Wasson R.G. 1957) documenting *velada*s of the local curandera, Eva Mendez (María Sabina). Mexico is now known as a centre of diversity for *Psilocybe* species. Guzmán *et al*. (2000) list over 50 species of *Psilocybe* species from Mexico alone. In comparison, probably due to indifference or taboo, the discovered species in Peru seem few, as do the number of species collected in neighboring countries.

Morchella Species

One stunning Moche ceramic has three mushrooms on its head (Fig18 a & b). Two of the mushrooms are sculpted on the side of the head with a light stipe, without annulus or volva. The brain-like cap appears oval to conical with light edges and darker interior groves. The representations most conform to specimens of the genus *Morchella* (Arora 1986), most probably *M. elata* (Fig.18 c) or *M. esculenta* (Fig.18 d). Both species have been found in the highlands of Peru (Pavlich M.R. 1976, Franquemont *et al*. 1990, Holgado *et al*. 2010).

Although there are dots painted on the fungi this is most probably not an *Amanita* due to the absence of a universal veil and its morphology. Instead, the fungus has the shape and the dots are likely to represent the darkened gaps between of the web-like spore-bearing tissues of the cap.

Morchella spp. are prized edible mushrooms by Quechua speakers around Cusco (Holgado 2010). Although we do not yet know its medicinal use in the Andes, *Morchella* species are used in other continents for medicinal purposes. For example, in traditional Chinese Medicine they are used to treat indigestion, phlegm, croup, and shortness of breath (Ying *et al*. 1987). Recent studies have also shown *M. esculenta* has anti cancer and oxidant properties. Stamets (2005) further mentions a *M. galactomannan* that illicites a positive immune response to macrophages.

Uncertainty: a Psilocybe or a Plutenoid mushroom

Figure 19 (a) shows a man with two mushrooms on his head. The one on the side of his head with a broad light stipe and dark brown enclosed cap appears to be a *Morchella* elata described previously (Fig. 18 d). The second mushroom with an inverted cap (Figs 19 a & b), provides a splendid insight into the craft and knowledge of ancient Peruvians of mushrooms species. Through the intricate representation of the picture we are told that the fungus in question has a cap appears flat conical, and lepitoid from this angle. The mushroom is sizable, about 5-10 cm wide with a stipe 10-15cm. This is a large mushroom. The gills are white or light colored, terminally bifurcate, and free or almost free from the stipe. Classical for free gilled fungi is that a portion of the pileus can be seen as a small ring at the top of the stipe as seen represented by ancient artists often presented as in a classic description of free gilled fungi (Largent 1974 p28). The stipe is slender brown without annulus ring, and we cannot see a volva. From its size, the mushroom looks may be young or mature. If it is young it could be either light or dark spored at maturity as do some *Psilocybe* species such as *P. semilanceata* (Fig 19c). If it is a mature specimen, the spores are most likely light colored. Few known *Psilocybe* species are so big or have brown stipes. It may be an as yet unidentified pluteotoid fungus. The lack of volva or annulus and brown stipe rules out it being an *Amanita* or a *Lepiota* species. It may still be a *Volvariella* species, which although it has a volva conforms to size and shape and more or less the color, and lacks an annulus (Fig. 19d). These have been found in the Andes (Pavlich 1976, Trutmann *et al*. 2012). The original ceramic would have to be examined for a better diagnosis.

Uncertainly: A mushroom with brown decurrent gills: Cortinoid?

An other fascinating mushroom structure found in Moche ceramics is the trumpet like mushroom, similar to the chanterelles, or *Cortinarius* species, such as *C. magnivelatus* (Fig. 20 a & b). There are a number of other possibilities. The mushrooms are characterized by an uplifted cap with brown, possibly decurrent or at least attached gills. It suggests the fungus has brown or dark spores). It has a short, robust brown stipe, perhaps with a ring. It is interesting that the two examples shown have dark brown caps decorated with symbols: either a hooked loop, or white spots reminiscent of the fly agaric. Both symbols suggest ritual religious use associated with sacred properties associated with *A. muscaria*. For these reasons it is presumed the fungus is entheogenic. However, its identify remains a mystery and reinforces the need for further study of macro fungi in Peru.

General Discussion

Evidence that mushrooms were used in pre Hispanic Peru

Although the scope of this study was limited, substantial evidence has been collected to demonstrate that ancient Peruvians extensively used mushrooms medicinally, religiously as well as mushrooms of high culinary value. We now know Peruvian ancestors were highly expressive in representing mushrooms in ceramics, textiles and sculpture representing them either realistically, or stylistically and symbolically. The extensive use of mushrooms in ancient Peru is in stark contrast to the mycophobia and apparent stigma that dominates modern Peruvian society and expressed by the virtual absence of literature on the subject in the country. Recent scientific advances have demonstrated the critical role fungi play as food, medicine and for ecosystem function (Stamets 2005). In hindsight, the change from a mycophilic to mycophobic society after the conquest may have had consequences on the wellbeing of the society as a whole and contributed to environmental degradation due to the devaluation of natural resources such as fungi. The extensive forests were cut or burned for pasture, building materials and fuel (Herreria A 2009) and indigenous peoples and their customs became slandered (Delgado Diaz del Olmo 1996). Even today many an indigenous person will only reluctantly tell you they eat mushrooms. Combining both the scientific evidence of the importance of fungi to human and environmental health with evidence of their historic importance in Peru will perhaps begin to revalue mushrooms. The discovery of the use in ancient Peru of mushrooms connects South American cultures with other cultures in the new world and old world, and to an ancient pan human belief system of which today we still find remnants (Wasson *et al*. 1986). Their redicovery as such reconnects Peru again to a long human tradition.

Cultures and initial timelines of mushroom use in Peru

It is highly likely that ancient Peruvians brought the knowledge of mushrooms with them as they migrated from the northern hemisphere, including the knowledge of edible, medicinal and sacred mushrooms. In this preliminary search evidence was found that as early as 1200 BCE they were important enough to be represented in the ceremonial and ritual art of the Cupisnique culture (1200-200 BCE) and Pucará cultures (1200 BCE -400 CE). Earlier petrographs representations have not been studied, evidence of mushroom use may be found caves. It places earliest Peruvian mushroom representations in the same timeline as early Meso American mushroom images of the Olmec 1000 BC (Borhegyi 2010). One can also trace mushroom use through a continuous dateline of cultures from 3000-2200 years ago to at least 1532 and geographically from the north to the south of the country through the Cupisnique, Pucará, Paracas, Moche, Wari, Chimú through to and finally the Inca cultures. With the destruction of Inca and indigenous societies after European contact, particularly their religion, representations of mushrooms by indigenous peoples virtually disappeared. New information shows that at least culinary use continues in some indigenous societies (Holgado *et al*. 2010, Trutmann and Luque 2011). The ancient power of mushrooms and symbolism however, remains embedded in indigenous myth and languages such as Quechua and Aymara. The root base of words are linked to power and the supernatural (Delgado Diaz del Olmo 1996). Words that identify specific mushrooms today day and their relation to their use in pre-Hispanic times remains to be investigated. Evidence from the few studies done independently suggest that similar nomenclature remain in indigenous languages (Franquemont *et al*. 1990), (Holgado Rojas M.E. *et al*. 2010, Trutmann and Luque 2011). However, none of the names of mushrooms commonly used seem to refer to the ancient sacred mushrooms. Yet, both Aymara and Quechua languages root words such as 'Calla' are derived from words that are derived from mushrooms that bestowed power. What happened to the use of these mushrooms and why were the names even forgotten or hidden? The ethno-mycology of Peru requires urgent study to enable better understanding of what remains of local knowledge of mushrooms and how it relates to historic knowledge and to better use it to help optimize the positive effects of fungal resources in Peru for wellbeing and better ecosystem function in an age of global change in mountains.

Identity of Ancient Mushrooms

The pre-Columbian mushroom representations were at times so realistic that they are able to be identified to genus and even species level. Thus far, those identified are *Amanita muscaria*, Morchella species, (probably *M. elata* or *M. esculenta*), *Calvatia* species (including *C. cynthiforma*) and one or more *Psilocybe* species, including one similar to *P. cubensis*. However, impressive as the mycological knowledge of the artist in pre Hispanic times was through the detailed representations of the mushrooms, often there are no known mushrooms to associate them to. Too little is known of the mushrooms that exist in Peru. This is due to the limited information on the extent and identity of mushroom in Peru. To date, largely due to resources, only a relatively limited number of mushrooms have been collected and identified in Peru and neighboring countries with similar ecosystems and very little ethno-mycology work has been conducted. Mycology in South America is only recently emerging beginning to be valued mainly due to commercial factors but also slowly, because of interest in the rich biodiversity of the region.

An other reason why it may be difficult to determine the identify the mushrooms found in ancient ceramics may be due to changes in the Peruvian landscape and traditions since Pre Hispanic days. There is evidence that human activity had great impact on vegetation even from the Holocene period (about 10,000 years ago) through burning and deforestation. (Bush *et al*. 2007, Bush & Flenley 2007 p45, Hansen *et al*. 1994) suggests that without human intervention the upper Peruvian Andes would have been forests of *Polylepis* up to 4000 m in the wet and 5000 m in dry areas. That said, it is known that in early colonial times there were still great expanses of forest in this sierra and Altiplano (Hyland 2004) and there was a great effort to reforest in Inca times. The destruction of forests was devastating in colonial times onward for firewood, construction and for pasture of imported livestock that denuded the Altiplano and the lowlands and destroyed soils & natural pasture through overstocking and erosion. The actions had and are having great effects of the ecology, the fertility of the landscape and probably on fungal communities as they did in the coastal lowlands. (Beresford-Jones 2004 Chapter 7). At least some of the fungi represented in ceramics, like *A. muscaria* and *Morchella* species are symbionts on trees or grow in woods. *Psilocybe* or *Panaeolus* spp. and *Calvatia* species are grassland species. However, some of the unidentified species may have been tree associated mushroom fungi that grew that may now be very rare or extinct.

Use of mushrooms in ancient Peru

It hard to divide mushroom use into single defined categories of use, since a single mushroom can be culinary, medicinal and can have 'spiritual' properties. Furthermore, to many indigenous groups there is little or no distinction between medicinal and spiritual. The more we find out about fungi the more we discover about their important properties and functions to humanity and environment.

Culinary

A number of mushrooms represented in ceramics are known culinary delicacies. Most notable are the species of the genus *Morchella*, (Franquemont *et al*. 1990, Holgado *et al*. 2010) and *Calvatia cynthiformis* (Holgado *et al*. 2010), Trutmann P. *et al*. 2012). Early colonial writings also show that mushrooms played an important and esteemed part in the lives of Pre Hispanic Inca society. Poma de Ayala (Poma de Ayala 1615) probably basing his writings on the knowledge of the 'legally dead' Jesuit friar Blas Valera (Nyland 2011) lists the Quechua names for types of mushrooms, 'c'allampa', 'concha' and 'Paku' as food. 'Paku' are large puffballs, including *Calvatia cynthiformis* represented in ceramics of various cultures. The local ethno-mycological knowledge and words are only now being collected. The above mentioned names are relatively generic, but they do provide a first order of categorization. Poma de Ayala, lists various mushrooms as part of the varied diet of people from the age of 30 during the Inca reign.

Medicinal

Shamanic like figures are commonly seen associated with mushrooms in artwork of the Paracas, Chimu and Moche. In the Paracas culture textiles we see spirit-like beings holding either mushrooms of various colors, or symbolic mushroom/tumis, often in shamanic flight. The flight associates them with entheogen use. They often also hold head trophies, which may associate them to the ritual of transformation, death and resurrection, perhaps to the Venus cults also found in Central America (Borhegyi 2010). In Moche culture we see mushrooms and symbols also associated with Lords and higher theocracy. The Lord of Sipán does not have mushrooms overtly growing out of his head, but the mushroom related symbolism is overwhelming, through his mushroom headdress, tumi, and symbols on his clothes, and ornaments with mushrooms. Other Moche representations show subjects with 'google' eyes indicative of trances, sometimes with facial expressions of fear.

It is still unclear from association of mushrooms with shamanic/curandero ceramic what the purpose was of representing some species. For example, morels were commonly represented. Yet, today morels are regarded in most cultures as a culinary delicacy rather than a medical herb. Still, there is information of their medicinal properties. Morels such as *M. esculenta*, are used to regulate the flow of vital energy, and have properties against tumors, expectorant, and gastrointestinal tonic (Hobbs 1986). Puff balls such as *Calvatia* spp. were used as an anti bleeding remedy, to sooth burns and itching and were anti-inflammatory agents (ibid). In fact, *Calvatia* species were regarded as magical by many indigenous groups in North America, and had many uses. *A. muscaria* for example had both visionary as well as medical properties, inhibiting tumors, epilepsy, and even eliminating ringworm (ibid). Current ethno-mycological information points to continued use of puffballs of *C. cyathiformis* and green spored *Lycoperdon wrightii* for medical purposes in Peru (Trutmann and Luque 2011).

Spiritual

What spiritual & religious role did mushrooms play in ancient Peru? In reality all that is known at this moment is that both *A. muscaria* and *Psilocybe* species appear to have been used since they are the only clearly known enthiogend represented. Yet, it is also known that these, and other as yet uncharacterized mushrooms, were consumed and used as entheogens since they associated with ancient flight of shamans and classic 'google' eyes of images. The ritual religious use of mushrooms by the theocratic class of Moche society is also implicated by use of mushroom symbols carried by high priests like the Lord of Sipán, eluding to ownership of power of these objects and thus properties of mushrooms.

To begin to answer the question of spiritual use of mushrooms in Andean society we need to refer to studies in other countries and continents. The nearest cultures studied were in Mexico and Guatemala, principally Maya and Aztec societies. It has been shown through representations by the Aztecs in the few documents surviving Spanish destruction (see the Vienna Codex) that at least *Psilocybe* species were used. *A. muscaria* is implicated in other representations. *Psilocybe* species were until recently still being used in various parts of Mexico in places such as Huautla de Jiménez, Oaxaca (Wasson et als. 1986). They were 'secret ' rites that were not normally discussed with outsiders. The principle use of spiritual mushrooms in such rites is to enable the connection to " the god within'.

Wasson (1972) noted: "*The bemushroomed person is poised in space, a disembodied eye, invisible, incorporeal, seeing but not being seen.... In truth, he is the five senses disembodied, all of them keyed to the height of sensitivity and awareness, all of them blending into one another most strangely, until, utterly passive, he becomes a pure receptor, infinitely delicate, of sensations*". "*It (the mushroom) permits you to see, more clearly than our perishing mortal eye can see, vistas beyond the horizons of this life, to travel backwards and forward in time, to enter other planes of existence even as the Indians say, to know God*".

How the spiritual use of mushrooms was used by ancient individuals, cults and religions is still unclear. In the case of *A. muscaria*, Borhegyi (Borhegyi 2010) proposed its central use in the veneration of Venus. He writes: "*The ideas thus generated included concepts of an alternate world with rebirth after death based on observation of the constant cycle of death and rebirth in nature. This included the predictable cycles of the sun and moon and veneration of the dualistic planet Venus based on its equally predictable cycle of death and rebirth as the Morning Star and the Evening Star. By the time the first native Mesoamerican religious texts appeared, whether in pictorial codices or, at the urging of various Spanish priests and chroniclers, in Spanish or one of the indigenous languages, there is evidence that this religion was identified with a supreme creator deity. This deity, seen early on as a double-headed serpent with bird and feline attributes, was known by different names at different times and in different indigenous languages and culture areas.*"

Even if his hypothesis is correct, is not clear if all ritual mushroom use, or certain species, especially *A. muscaria*, were associated with Venus veneration, but much of the Pre-Columbian art associated with mushrooms also contain symbolism of what Borhegyi (2010) would regard as the Venus cult. For example, one finds the hook symbol, the fives, the double star associated with Venus (the morning and evening star), symbols of transformation, death and resurrection. Although, other variants can't be ruled out for the time being Borhegyi's proposal it is a reasonable hypothesis, particularly since it explains and provides meaning to the symbolism of many ceramics and textile representations that thus far are missing.

It appears that changes did take place in the preference of entheogens in ancient Peru. As societies like the Paracas culture changed over time to one like the Nasca, other entheogenic agents appear to have become more represented than mushrooms. At least, identifiable mushroom symbolism appears much reduced in the Nasca art. Similarly, it clearly changes took place in Moche society, from one where mushrooms were vividly represented to one predominated by realistic representations of San Pedro and where only symbolic or Iconographic symbols of mushrooms like the golden crescent and tumi are found. Either mushrooms were substituted in later phases of societies, or mushrooms went out of common use into the exclusive hands of the elite who replaced it for commoners with a common plant, the San Pedro cactus. Inca society used Coca as its holy plant. Its production was strictly controlled by the elite, but made available to the commoner. Coca rather than mushrooms are mentioned by the Spanish chroniclers Yet, golden mushrooms earrings are found in the Yale Collection from Machu Pichu. Furthermore, Inca myths point to conical golden and other red mushrooms, suggesting that perhaps spiritual mushrooms use was the realm of the elite theocracy and groups like the 'Callawara". The legendary Inca bearers.

The changes that favored entheogen use between societies over time could also have been associated with the rise and fall of trade with Meso America, where entheogenic mushrooms like *A. muscaria* grew. As mentioned earlier, *A. muscaria* has not as yet been collected and identified in Peru, and the range of its common tree-hosts are limited mostly to the northern hemisphere. We know that there was substantial trade with Meso America, although we do not know how consistent this trade was over time. Perhaps, there were times when trade was limited that other entheogens were preferred such as San Pedro, ayahuasca and to a lesser extent coca? The topic requires more research for clarification.

Conclusions

This preliminary study on the use and importance of mushrooms in ancient Peru has illuminated fascinating areas of the lives of people that are now forgotten, neglected or devalued by the bulk of the Peruvian population now living in cities the lowlands. The study has implications for the rest of South America, insofar that it is evident that indigenous peoples in other parts of South American used mushrooms. Velandia (2008) already wrote of mushroom symbolism in Colombia. Snuff boxes with mushrooms have been found in Argentina (Torres 1996), and symbols are found on vases and information about the Mapoche exist from Chile. These make it clear that ancient people in other parts of south America were acquainted sufficiently with mushrooms, and associated symbolism to represent their ceramics. In the future, studies should extended to explore not only to explore Peruvian mushrooms further, but be extended to include other South American countries. In this manner a holistic understanding can be constructed of their importance to the lives of ancient Americans.

There is a need to more thoroughly look at each Peruvian culture and even look at pre-ceramic sites to obtain a better timeline of mushroom use. For example, changes in Moche mushroom use and symbolism should be studied using not only the IV phase ceramics often used (Castillo *et al*. 2007)). Using this study as a base, thre is a need to look for a direct link between ceramics and actual identification of mushrooms from archaeological sites. In other words to not only evaluate ceramic bowls for plant material and pollen but also for fungal remnants and spores. If fungal material can be found then it may be possible to further identify fungi and to explore genetic similarities using molecular techniques. In addition, there is an abundance of symbolism associaed with mushrooms. Global Mountain Action (2011) has begun to document this aspect and will publish these results in a second publication in this series.

The question of what happened to mushroom use in Peru in post conquest times requires elucidation in order to better understand the current state of disinterest. What happened to the knowledge and mushroom use and why did it happen? It is known that Catholicism and colonial politics were important factors in Meso America that devalued mushroom consumption and demonized its use there (Wasson 1972, Borhegyi 2010). Did the same happen in Peru? Global Mountain Action (2011) has begun a rapid survey and will publish this base material as part of this series. It is hoped the information will stimulate more in depth studies.

Just as botanical input has greatly influenced the advances in field of archaeology more mycological input is urgently needed to obtain a more accurate understanding of the ancient Peruvian world. There is also a great urgency to use mycology understand better current and in post conquest use and knowledge of mushrooms in Peru. A few studies have been reported on these themes. Franquemont *et al*. (1990) reported names of a few mushrooms in Quechua and identity in a study in Chinchero, close to Cusco. More recently, Holgado *et al*. (2010) and have published an article on the identity and Quechua names of some local mushrooms around Cusco and local culinary use. These studies are beginning to shed light on the rich knowledge and the place that mushrooms have in indigenous communities that hitherto were forgotten in national or international assessments for food security and research needs, with exception of the United Nations Food and Agriculture Organization that conducted a worldwide study that included Peru (Boa 2004). The FAO study although commendable in its worldwide scope, is of questionable value for Peru, other than exposing the paucity of information, and confusing due to highly questionable list of references. For example, Remotti C.D. and Colan, J.A. 1990, Identification of wild edible fungi in Dantas Forest, Huanuco. Revista Forestal del Peru 17: 21-37 does not appear to have been printed in this journal but has been used by various authors, and Diaz (2003 pers communication) seems a questionable reference to commercial use of *Boletus edulis*, since only *Suillus luteus* from introduced Pine plantations has thus far been used commercially.

More broadly, there is an fundamental need in Peru to invest more in research on fungal diversity to collect, characterize fungi and mushrooms to obtain a clearer picture of the roles in the Andean environment. Without knowledge of the current diversity ancient fungal material will not be able to be classified and placed into context. Present knowledge of genera and species is still limited despite commendable efforts of the few fungal taxonomists in Peru and surrounding countries. Most of the Peruvian Andes, the Selva and the lowlands have not been systematically studied. Only two mayor studies exist of fungi and these were concentrated principally in the Selva and Amazonian basin (Pavlich M.R. 1976, Espinoza M. 2003, (Mata *et al*. 2006). There has been little interest in mycology and taxonomic studies in national institutions due to limited potential of funding from national and international sources. The neglect of mycological studies by national and international agencies is surprising since extensive funding has been made available for studies under the umbrella of the documentation of genetic diversity for pants and animals in Peru in what is regarded as one of the most genetically diverse countries in the world. Due to the key role of fungi for human and environmental health and well-being especially in mountain regions, Global Mountain Action (2011) has made the the theme a priority.

Bringing together knowledge of Ancient use of mushrooms with present local and scientific knowledge should help further understanding of the culinary, medicinal and spiritual properties of mushrooms. In a time of worldwide reflection on the sustainability of western lifestyles and the dire state of the extreme consumerism driven economic models, out of control financial opportunism with severe global environmental consequences, a better understanding of ancestral holistic use of mushrooms in diets and rituals may be of value in itself to bring life again in equilibrium with the environment and provide meaning. Peru has already become a spiritual Mecca for many seeking ancient Andean knowledge.

Acknowledgements

I would like to thank Ulla Holmquist and the Museo Larco, Lima for the interest and help, especially by enabling access to their extraordinary online collection database; to Dr. John Henderson and Dr. David H. Thurston of Cornell University, who took time to read a draft of this document and provided valuable comments and suggestions. I'm also grateful to the many collections whose items I found on the internet and authors of images whose names I have not been able to find. Thanks to Carl de Borhegyi, whose fascinating online study on 'unlocking the mushroom code' made me realize how little was known about ancient use of mushrooms in Peru and South America. Finally, this work is dedicated to the ancient Peruvians, in the hope that with this work a little of what was lost and sacred has again been found. I Thank you.

Biosynthesis of Psilocybin

Part II, Incorporation of Labelled Tryptamine Derivatives*

by

* Part I. Ref. 5.

The biosynthesis of psilocybin has been investigated by feeding labelled precursors to *Psilocybe cubensis*. The following specifically labelled compounds were synthesized: psilocin-^{3}H, 4-hydroxytryptamine-^{14}, *N,N*-dimethyltryptamine-^{14}C and -^{14}-^{3}H, *N*-methyltryptamine-^{14}C-^{3}H and DL-tryptophan-^{3}H. A number of other indoles were labelled by acid catalyzed exchange in tritiated water. The experimental data suggest a sequence: tryptophan → tryptamine → *N*-methyltryptamine → *N,N*-dimethyltryptamine → psilocin → psilocybin. The fungus can also by an alternative route convert 4-hydroxytryptamine to psilocybin. Large differences in the rate of absorption of different closely related precursors has been observed.

Mushrooms containing the hallucinogenic compounds psilocybin (XVI) and psilocin (IV) have long been used as intoxicants by the natives of Mexico. The compounds are closely related 4-hydroxylated indole derivatives[1] and occur mainly in members of the genus *Psilocybe*. The production of psilocybin in *Psilocybe* species in submerged culture was successfully accomplished by Catalfomo and Tyler Jr.[2] and recently also by Leung *et al*.[3]

Brack *et al*.[4] found that psilocybin was biosynthesized from tryptophan in still cultures of *P. semperviva*. In our previous study[5] we found that submerged cultures of *P. cubensis* effectively incorporated also tryptamine into psilocybin.

The present study was undertaken to clarify the sequence of events which leads from tryptophan to psilocybin. This sequence will involve the following modifications of tryptophan in a definite or alternative order: decarboxylation, *N*-methylation, 4-hydroxylation, and *O*-phosphorylation (Fig. 3).

To elucidate this pathway we have used two approaches. In the present study we have investigated the incorporation into psilocybin of labelled hypothetical intermediates. The subsequent paper[6] is concerned with a study of the conversion of tryptophan to psilocybin and the isolation of "apparent intermediates" in this process.

Experimental

Melting points were determined with an electrically heated metal block using calibrated Anschütz thermometers. Infrared spectra of synthesized labelled compounds were recorded with a Perkin-Elmer 237 spectrophotometer and if possible compared with references.

Sodium cyanide-^{14}C, L-tryptophan-G-^{3}H, DL-tryptophan-1'^{14}C, and methyl iodide-^{14}C were purchased from the Radiochemical Center, Amersham, and LiAlH$_4$-^{3}H and tryptamine-2'-^{14}C bisuccinate from New England Nuclear Corporation Boston. The purity of the commercially available and synthesized labelled compounds was checked by thin-layer and paper chromatography followed by scanning in a chromatogram scanner.[7] When necessary, labelled intermediates and final products were purified by preparative paper[5] or column[6] chromatography. Reference materials were obtained from Calbiochem, Los Angeles; Sandoz AG, Basel; and Koch-Light, Colnbrook.

Psilocin-2'-^{3}H (IV). Fig. 1.

*4-Benzyloxy-3-(*N,N*-dimethylcarbamoylmethyl)indole* (II) was prepared from 4-benzyloxyindolyl-(3)-acetic acid (I) *via* the acid chloride.* Yield 64%; m.p. 180-181°. Reported[3] m.p. 175-178°.

4-Benzyloxy-3-(2-dimethylaminoethyl)indole-2'-^{3}H (III). 0.7 g II (2.28 mM) in 20 ml dry tetrahydrofuran was slowly added to 0.35 g (9.24 mmoles) tritiated $LiAlH_4$ (2.5 mC) in 20 ml tetrahydrofuran. After one hour at 40°, 5 ml water was added and the mixture stirred for 20 min. 15 ml of 20% NaOH was added and the trubid solution was extracted with ether. After drying over Na_2SO_4 and evaporation of solvent, the residue crystallized. Yield 0.55 g (84%); m.p. 120-121°. Reported[8] m.p. 120-121°.

Psilocin-2'-^{3}H (IV) = 3-(2-methylaminoethyl)-4-hydroxyindole-^{3}H. 0.5 g III (1.9 mmoles) in 25 ml methanol was debenzylated with H_2 and 0.3 g 5% Pd on Al_2O_3 in a Parr hydrogenation apparatus for 4h. After filtration with Celite, the solvent was evaporated yielding 0.21 g (54%) blue crystals, m.p. 169-170°. Recrystallization from methanol did not change the melting point. Reported[8] m.p. 168-170° and [1] 173-176°. Spec. activity 261 µC/mM.

4-Hydroxytryptamine-2'-^{14}C (VII) Fig. 1.

4-Benzyloxygramine [9] was quaternized with dimethylsulfate to 4-benzyloxygramine methosulfate (V) according to Schöpf and Thesing.[10] Yield 90%; m.p. 144-145°. Reported[11] m.p. 143-144°.

4-Benzyloxyindolyl-(3)-acetonitrile-2'-^{14}C (VI). 2.7 g V (6.65 mmoles) and 0.22 g $Na^{14}CN$ (0.4 mC; 4.43 mmoles) was dissolved in 25 ml water in an ampoule, which was scaled and heated on a steam bath for one hour. The nitrile separated as an oil. The ampoule was cooled and the mixture extracted with chloroform. The extract was dried over Na_2SO_4 and the solvent evaporated, affording 0.9 g (53%) pale yellow oil, which was used in the next step without purification. IR: 2250 cm^{-1} (C≡N).

4-Benzyloxytryptamine-2'-^{14}C. 0.9 g VI was reduced with 0.3 g $LiAlH_4$ as described for II. Yield 0.51 g (57%), oil, which did not crystallize. Hydrogen oxalate: m.p. 114-116°. Reported[9] m.p. 117-120°.

4-Hydroxytryptamine-2'-^{14}C (VII). The previous compound was debenzylated as described for III to give 84% of an oil that did not crystallize. Oxalate m.p. 261-264°. Reported[9] m.p. 269-270°. Spec. activity 87 µC/mmole as base.

N,N-Dimethyltryptamine-2'-^{14}C

3-Indoleacetonitrile-2'-^{14}C was prepared from 4.5 g (15 mmoles) gramine methosulfate[10] and 0.5g $Na^{14}CN$ (0.25 mC; 10 mmoles) in 25 ml water as described for VI. Yield 1.2 g (77%) of an oil, which was used in the next step without purification. IR: 2250 cm^{-1} (C≡N).

3-Indoleacetic acid-2'-^{14}C was prepared from the nitrile by alkaline hydrolysis.[12] Yield 70%; m.p. 162-165° (decomp.), reported[11] m.p. 165-166° (decomp.).

*3-(*N,N*-dimethylcarbomoylmethyl)indole-2'-^{14}C* was prepared from indoleacetic acid-2'-^{14}C by the method used for II affording an oil (yield 87%) which was used in the next step without purification.

N,N-*dimethyltryptamine-^{14}2'-C = 3-(2-dimethylaminoethyl)indole-^{14}C*. 0.25 g of the amide was reduced with 0.2 g $LiAlH_4$ as described for II. Yield 0.147 g (62%) base as a pale yellow oil. Its hydrochloride melted at 159-163° after recrystallization from ethanol and ether. Reported[13] m.p. 166-167.5°. Spec. activity 75 µC/mmole.

N,N-Dimethyltryptamine(-indole-^{3}H-*N*-methyl-^{14}C) (XII). Fig. 1.

*3-(*N*-Benzyl-*N*-methylcarbamoylmethyl)indole* (IX) was prepared from (1.6 mC) 3-indoleacetic acid-indole-^{3}H (VIII) and *N*-benzyl-methylamine as described for II. Yield 71%; m.p. 149-150°.

1.0 g of IX was reduced as described for II with $LiAlH_4$ in tetrahydrofuran to yield (86%; 0.97 mC) N-*benzyl*-N-*methyltryptamine-^{3}H* (X).

0.80 g of X dissolved in 15 ml ethylacetate was quaternized with 0.5 g methyl iodide (0.1 mC) in an ampoule at 100° for one hour.[8] The crystalline deposit was washed with ethylacetate and then dissolved in 50 ml of 50% aqueous methanol. This solution was treated with freshly prepared AgCl [8] to convert the iodide to the chloride (XI).

A solution of XI in 25 ml dry methanol was debenzylated as described for III. After column chromatography 0.31 g of the pure, doubly labelled *N,N*-dimethyltryptamine (XII) was obtained with a spec. activity: ^{3}H 320 µC/mmole; ^{14}C 11.2 µC/mmole. m.p. 43-45°; reported[17] m.p. 48-49°.

N-Methyltryptamine-1'-^{14}C-N-methyl-^{3}H (XV). Fig. 1.

Tryptamine-1'-^{14}C (XIII) 0.21 g (0.02 mC; 1.3 mmole) was formylated with 0.18 ml formic acid in 0.41 ml acetic anhydride according to Stauffer.[14] The *N*-formyltryptamine (XIV) was reduced with 0.4 g $LiAlH_4$ in refluxing tetrahydrofuran for 12 h to yield 0.10 g (44%) of *N*-methyltryptamine-1'-^{14}C (XV). Spec. activity 8.0 µC/mmole.

N-formyltryptamine (0.24 g) was similarly reduced with $LiAlH_4$-^{3}H (0.10 g; 0.5 mC) to *N*-methyltryptamine-*N*-methyl-^{3}H. Yield 0.10 g (47%). Spec. activity 66.0 µC/mmole.

N-*methyltryptamine-(1'-^{14}C-*N*-methyl-^{3}H) = 3-(2-methylaminoethyl)-indole-^{14}C-^{3}H* (XV) was obtained by mixing ^{14}C-labelled with ^{3}H-labelled compound.

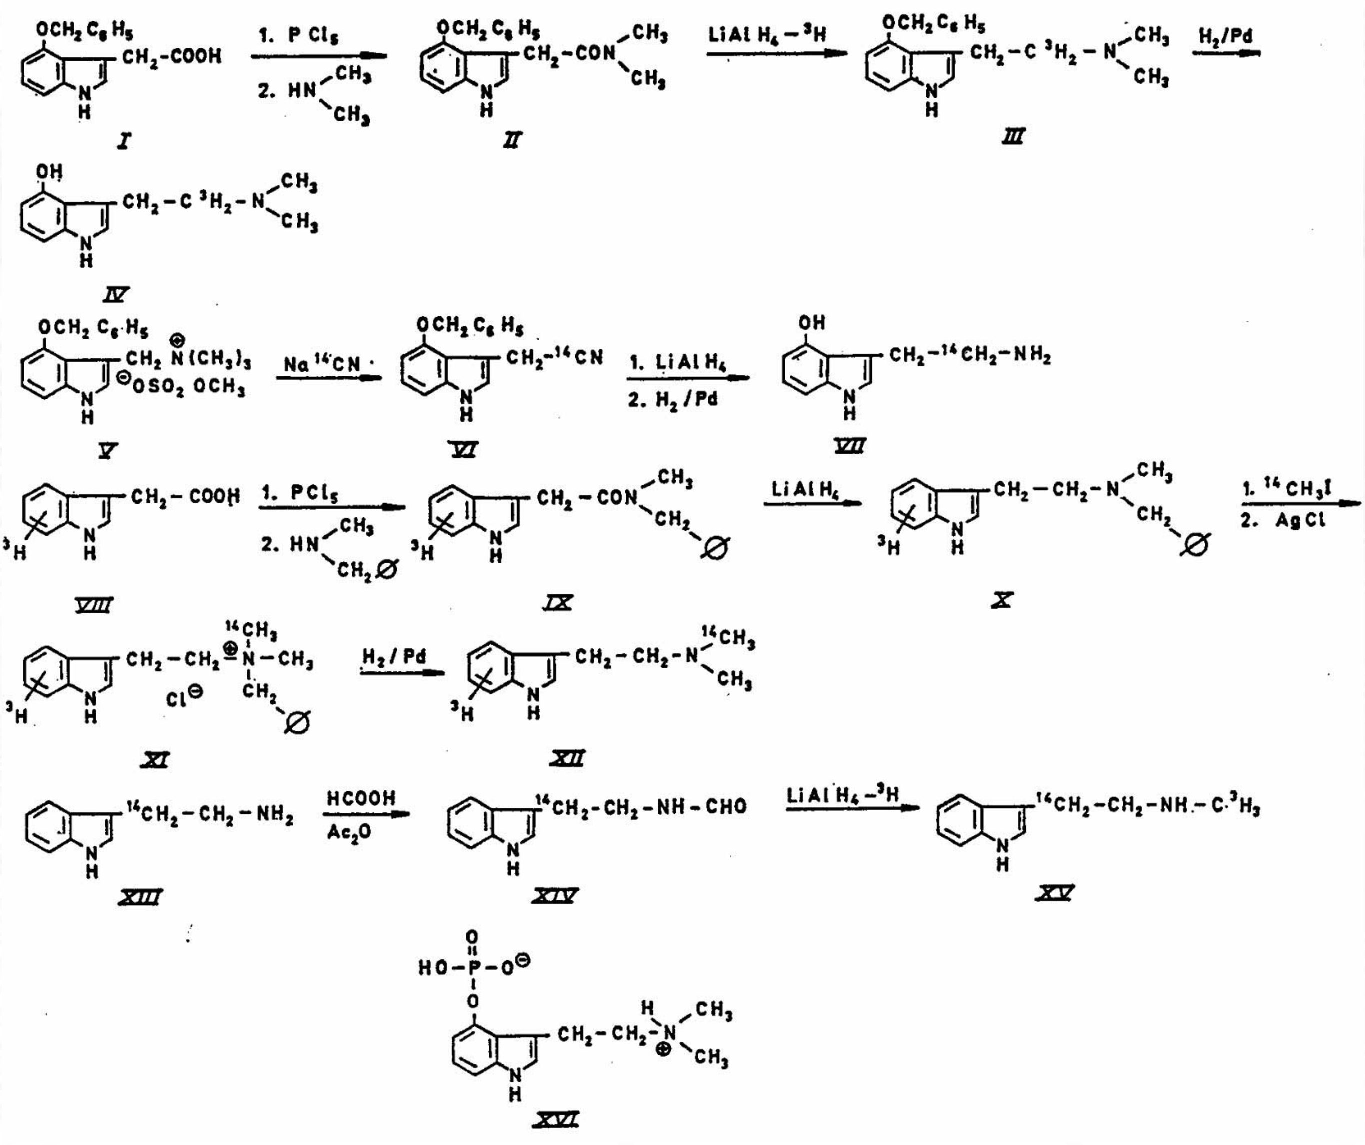

Fig. 1. Synthesis of ^{14}C- and ^{3}H-labelled precursors.

Other compounds

DL-*Tryptophan-2'-^{3}H* Gramine 1.74 g (10 mmoles), 2.60 g (12 mmoles) ethyl acetamidomalonate and 0.20 g powdered NaOH in 30 ml dry toluene[15] were refluxed for 14 h under N_2. The hot solution was filtered and upon standing overnight, 2.52 g (73%) of ethyl α-acetamid-α-carbethoxy-β-(3-indole)-propionate was deposited. This compound (2.0 g) was saponified and decarboxylated[18] in tritiated water (25 mC) to DL-tryptophan (alanine-2'-^{3}H) which was crystallized from aqueous ethanol. Yield 0.23 g (19%); m.p. 279-281°. Reported[16] m.p. 281-285°. Spec. activity 293 µC/mmole.

Generally tritium labelled compounds. 0.1 g of the aromatic compound to be tritiated was dissolved in 0.5-1 ml tritiated water (200-500 mC/ml) in an ampoule and the mixture was saturated with HCl gas. The sealed ampoule was treated on a steam bath for one hour. The evaporated residue was repeatedly dissolved in methanol to exchange labile hydrogens. This acid catalyzed exchange procedure will exchange predominantly the hydrogens of the indole nucleus.[16] The crude tritiated product was purified by preparative paper[5] or column[6] chromatography. The purified amines were dissolved in dilute acid together with 2-4 times the amount of carrier material. After the addition of alkali, the amines were extracted with benzene and crystallized as base or hydrochloride.

4-Benzyloxytryptophan was tritiated in about 1 N HCl-solution to minimize the destruction and debenzylated as described for III. It was purified in system BAW.[5] The tritiation of 3-indoleacetic acid (0.16 g in 1.5 ml of 50% aqueous methanol; 140 mC) gave a particularly pure and highly labelled compound.

Specific activities: Tryptamine-^{3}H: 43.5 µC/mmole; *N*-methyltryptamine-^{3}: 810 µC/mmole; *N,N*-dimethyltryptamine-^{3}H: 161 µC/mmole, DL-4-hydroxytryptophan-^{3}H: 96.1 µC/mmole; 3-indoleacetic acid: 1.8 mC/mmole.

Other conditions

Culture conditions etc. The method for submerged biosynthesis of psilocybin by *P. cubensis*, introduction of precursors and the isolation, purification and recrystallization of psilocybin are described previously as well as different assay procedures.[5]

Psilocybin was isolated as described[5] by methanol extraction, ion exchange technique and finally preparative paper chromatography. The following criteria[5] were used for determination of incorporation of label from a precursor into derived psilocybin: by TLC (in MAW), by paper chromatography (in LAW and BAW), and by electrophoresis followed by scanning, it was shown that the radioactivity was firmly associated with the isolated psilocybin and finally after the addition of carrier psilocybin (7-10 mg), psilocybin was crystallized from hot methanol to constant spec. activity.

To minimize the individual differences in incorporation rates between different cultures, a number of experiments were carried out (Table 1), where two different precursors, one ^{3}H-labelled, the other ^{14}C-labelled, were introduced into the same culture.

Chromatographic methods. The chromatographic systems have been described earlier.[5] Paper chromatography on Whatman 3MM paper with the following solvent systems BAW: butanol-acetic acid-water (4:1:5); IAW: isopropanol-conc. NH_4OH-water (8:1:1). TLC on Silica Gel G in system MAW: methanol-acetic acid water (75:10:15). 4-Hydroxytryptamine which was not included in the previous paper[5] has the following R_F-values: in system BAW: 0.85; in system MAW: 0.75; and has a similar mobility as psilocin in the electrophoretic system. Psilocybin from 4-hydroxytryptophan-^{3}H fed cultures was isolated after purification first in system IAW and then in system BAW.[5]

Uptake of precursors from medium. About 1.0 mg of labelled precursor was introduced into each of two cultures. At zero time and then at different time intervals (Fig. 2) samples were withdrawn aseptically and the radioactivity in 500 µl of the medium was determined. To determine the percentage of radioactivity still present as the originally introduced compound, an aliquot of the medium, if necessary after concentration by lyophilization, was separated in systems MAW (Eastman chromatogram sheet) or BAW. Strips of the chromatogram were counted in a liquid scintillator.

Table 1. Incorporation of labelled precursors into psilocybin.

Expt. No.	Precursor introduced	D.p.m. x 10^{-6}	Mg	Precursor incorporated into psilocybin, %; (mg psilocybin formed)	Spec. act. of psilocybin µC/mmole	Dilution[a]

[a] - Spec. act. of precursor/spec. act. of psilocybin.
[b] - For location of label, see Experimental section.
[c] - Signifies that two differently labelled precursors were introduced into the same culture.

Results and discussion

Labelled precursors. Psilocin-^{3}H, 4-hydroxytryptamine-^{14}C, *N*,*N*-dimethyltryptamine-^{14}C and -^{14}C-^{3}H, *N*-methyltryptamine-^{14}C-^{3}H, and DL-tryptophan-^{3}H were synthesized by appropriate modifications of known procedures[8,9,12,14-16] as illustrated in Fig. 1, to give suitably, singly or doubly, specifically labelled compounds. *N*-Methyltryptamine-*N*-methyl-^{3}H was conveniently prepared from tryptamine by formulation and reduction of the *N*-formyltryptamine with tritiated LiAlH$_4$. Ring tritiated *N*,*N*-dimethyltryptamine-^{3}H (as the benzyloxy compound), and 3-indoleacetic acid-^{3}H were obtained by acid catalyzed exchange in tritiated water.

Biosynthesis of psilocybin. A number of alkaloids (*cf*. Ref. 22) contain an indole nucleus hydroxylated in position 4 (*e.g*. venanatine,[5] psilocin), in position 5 (*e.g*. ibogaine, eserine), in position 6 (*e.g*. reserpine, vindoline), in position 7 (*e.g*. aspidospermine, vallesine) or in more than one position. Several indole alkaloids have been demonstrated to be derived from tryptophan.[23] However, one of the still lacking, interesting points in our knowledge is whether this hydroxyl group is introduced into tryptophan or if the hydroxylation of the indole nucleus occurs during some later stage as a result of secondary conversions of the formed alkaloid skeleton.

Psilocybin is derived from tryptophan[4,5] but it is not known in which specific sequence, if any, the necessary modifying reactions (decarboxylation, *N*-methylation, 4-hydroxylation, and *O*-phosphorylation) occur. For the biosynthesis of psilocin, one could suggest analogies in the biological formation of serotonin and gramine. The latter compound is derived from tryptophan by a dealkylation to 3-aminomethylindole followed by step-wise *N*-methylation.[19,20] Serotonin is biosynthesized, as numerous investigations have shown, from tryptophan *via* 5-hydroxytryptophan,[21] thus, initially, by a hydroxylation of tryptophan followed by a decarboxylation.

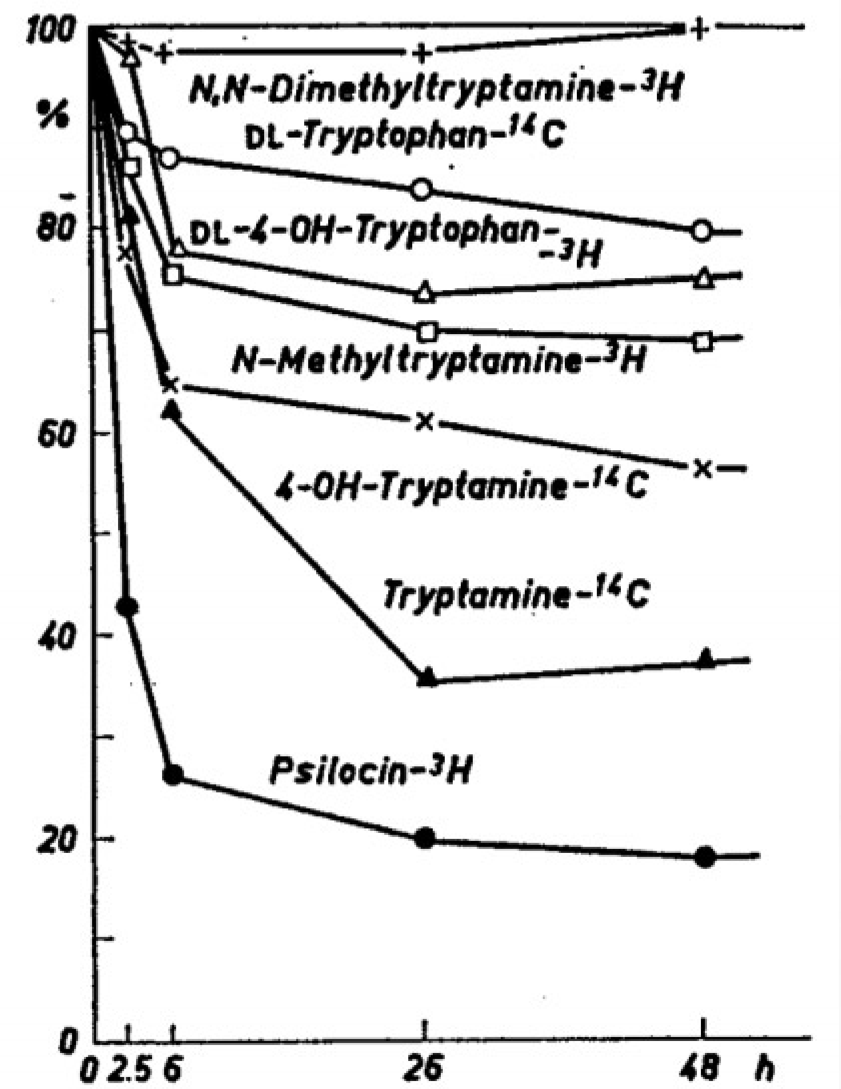

Fig. 2. Up-take of precursors from medium by *P. cubensis*. Per cent of introduced radioactivity remaining in medium.

However, the results in Table 1 show that 4-hydroxytryptophan which so far has not been encountered in nature, in contrast to tryptophan does not function as a precursor of psilocybin. Tryptamine, which is readily formed from tryptophan by *P. cubensis*,[6] serves as a better precursor of psilocybin than tryptophan. If tryptamine is methylated to *N*-methyltryptamine, this is an even better progenitor of psilocybin with incorporations showing that more than half of the psilocybin was derived from the introduced labelled precursor (Expts. Nos. 38, 42). The corresponding dimethyl derivative *N,N*-dimethyltryptamine may, however, be considered as a poor precursor as judged from the incorporation percentages. These are decidedly lower than for *e.g.* tryptophan and definitely not in agreement with *N,N*-dimethyltryptamine standing biogenetically closer to psilocybin than does tryptophan.

Nevertheless, with other factors taken into account the low incorporation percentages for *N,N*-dimethyltryptamine does not make it an unlikely intermediate. If the "dilution factors" for this compound and for psilocin (Expts. Nos. 21, 27) are compared, it is evident that psilocin is about ten times more effectively incorporated into psilocybin. This large difference led us to investigate the up-take of different precursors from the culture medium by the fungus with the striking differences shown in Fig. 2. A the time when the labelled compounds are administered, 12-15% of the culture volume is taken up by the cells. This means that *N,N*-

dimethyltryptamine (Fig. 2) actually to some extent is prevented from entering the cells, since in this and two other experiments at any time no more than 7% of this labelled material, usually much less, had disappeared from the liquid medium. This poor absorption of the precursor was verified by the low activity present in the methanol extract of the fungus.

The activity of administered non-hydroxylated indoles remained in the medium, as shown by TLC, still mainly (not less than 74%) as the originally administered compounds after 44 h. The pH of the medium was, as could be expected, crucial for the stability of the 4-hydroxylated indoles. The pH of the culture medium is at start 5.2 and is then slightly decreasing to 4.8-5.0 between the 4th and 10th day and increases then slowly. This means, however, that during the experiments the 4-hydroxylated indoles have a reasonable stability. Thus psilocin remained unchanged to 63% after 44 h in a medium of pH 5.2 but was quickly destroyed at a pH over 7.

The curves in Fig. 2 show, as expected, that the up-take is most rapid at the beginning, reaching a maximum after about 24 h followed by a slow, small (less than 10%) release of radioactivity back into the medium over the next 96 h. If the points on the initial parts of the curves are used to get a rough estimate of the clearance of the precursors from the medium, the following approximate half-lives are obtained for: psilocin = 2 h, tryptamine = 8 h, tryptophan = 16 h, and *N,N*-dimethyltryptamine over 40 h.

The above data would suggest the following sequence (Fig. 3) for the formation of psilocybin:
tryptophan → tryptamine → *N*-methyltryptamine → *N,N*-dimethyltryptamine → psilocin → psilocybin.

Experiments with doubly labelled *N*-methyltryptamine and *N,N*-dimethyltryptamine are in progress to ensure that these compounds are converted *in tot* to psilocybin without previous demethylation.[24]

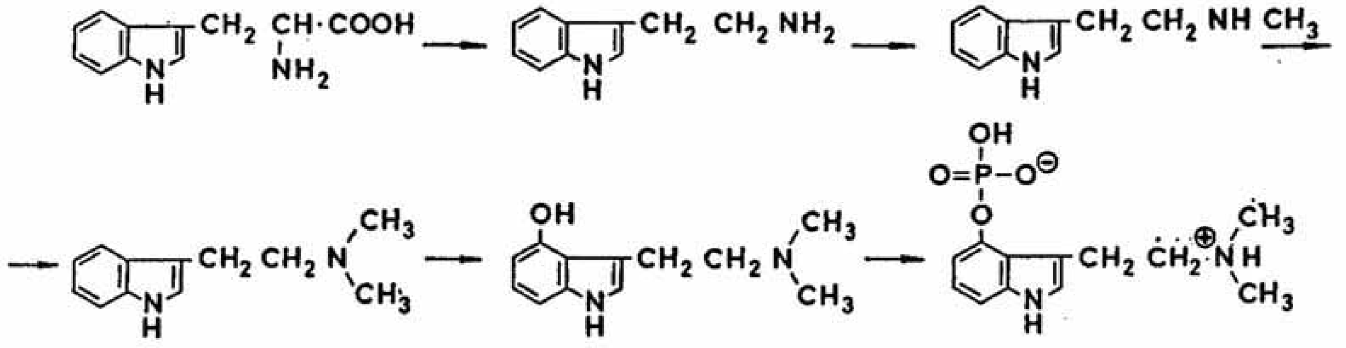

Fig. 3. A possible pathway of psilocybin biosynthesis as indicated by present experiments.

The data in Table 1 also indicate that the fungus can utilize another path to psilocybin since also 4-hydroxytryptamine is well incorporated into psilocybin. Here, the hydroxyl group occurs already at the tryptamine-stage thus before the *N*-methylation steps. It may be noted that 4-hydroxytryptamine apparently is a metabolite of 4-hydroxytryptophan in animals.[21] When 4-hydroxytryptamine was introduced into the culture, this occasionally led to the formation also of small amounts of one or two "psilocybin-like" compounds which possibly may have been phosphoric esters of 4-hydroxytryptamine and its *N*-methyl derivative, the recently isolated baeocystin.[25]

Thus it appears the *P. cubensis* can utilize two pathways to psilocybin. Further experiments with *N*-methyl-4-hydroxytryptamine-^{14}C-^{3}H and doubly labelled tryptamines as well as experiments on "apparent intermediates" which are now in progress[6] are required to show if the fungus normally uses more than one pathway from tryptophan to psilocybin. So far, only tryptamine and psilocin have been isolated from the fungus as "apparent intermediates" in this process.

Acknowledgements. This study was supported by the *Swedish Natural Science Research Council*. The technical assistance of Miss B. Jerkeman is appreciated. Dr. A. Hofmann, Sandoz AG, kindly supplied psilocybin.

Psychotomimetic mushrooms have long been employed as intoxicants by various native peoples. Schultes[10] describes their employment in magico-religious ceremonies by the Indians of Mexico and Central America, and extensive documentation of such usage has been provided by the Wassons[14,15] and by Heim and Wasson[6].

Especially noteworthy is the occurrence of certain indole derivatives in many of the basidiomycetes to which psychotomimetic properties have been ascribed. Several species of *Panaeolus* contain serotonin (5-hydroxytryptamine), first demonstrated in a fungus, *Panaeolus campanulatus* (Fr.) Quel., by Tyler[13]. Bufotenine (5-hydroxy-*N*,*N*-dimethyltryptamine) was shown to exist in *Amanita citrina* (Shaeff.) S. F. Gray [*Amanita mappa* (Lasch) Quel.] by Wieland and Motzel[16]. Psilocybin (4-phosphoryl-*N*,*N*-dimethyltryptamine), was first found in *Psilocybe* species by Hofmann, *et al.*[8] The latter two principles are the most recently discovered hallucinogens in basidiomycetes and are of particular interest since they are the only principles isolated from mushrooms which are capable of inducing psychotomimetic effects in human beings following oral ingestion.

Heim, *et al.*[7], established conditions favoring the formation of both sclerotia and sporocarps from mycelial growth obtained upon subculture of the spores and tissue of the naturally occurring Mexican *Psilocybe* species. In this way they obtained ample amounts of materials for isolation and structural studies of the active principles. The psychotomimetic effects on human beings following ingestion of either the wild-grown sporocarps or sporocarps, sclerotia, and mycelium produced in laboratory culture were identical[9]. Singer[11] and Stein[12] obtained similar results, but neither they, Heim, *et al.*[7], nor Hofmann, *et al.*[8], studied the production of psilocybin or psilocin in submerged culture fermentations. This constituted a major a major objective, and data presented herein were derived from submerged culture fermentations of *Psilocybe* species.

Experimental evidence regarding the biosynthesis of psilocybin or psilocin is quite limited. The structural similarity between these compounds and tryptophan suggested they might derive from that common amino acid. Part of the psilocybin isolated from the surface-cultured mycelium of *Psilocybe semperviva* Heim & Cailleux by Brack, *et al.*[2], was derived from the isotopically labeled tryptophan added to the nutrient medium. An additional objective of the present study concerned the fate of tryptophan added to replacement culture media containing washed mycelial pellets from submerged culture fermentations.

Material and Methods

Culture techniques. - Mycelial cultures of the organisms investigated were maintained on potato-dextrose-yeast agar slants[1]. The compositions of the nutrient medium (medium no. 1) and the replacement medium (medium no.2) are given in table 1. Various modifications of these media will be described subsequently.

For shaken-flask studies, transfers were made from agar slants to 125-ml Erlenmeyer flasks containing 30 ml of the desired medium. After four to seven days on a shaker at 25±1°C, the mycelial growth (pellet form) was homogenized in a sterile semimicro Waring Blendor for fifteen seconds and 5 ml per 100 ml added as inocula to all experimental flasks. Unless otherwise noted, flasks were then shaken at 25°C for periods of five to fifteen days.

Table 1. Nutrient media

Basic Nutrient Medium Medium no. 1	
Ammonium succinate	1.0 Gm
Glycine	9.0 Gm
Glucose	5.0 Gm
Yeast extract	0.5 Gm
KH_2PO_4	0.1 Gm
Thiamine hydrochloride	0.003 Gm
$(NH_4)_6Mo_7O_{24}$-$4H_2O$	0.05 mg
$ZnSO_4$-$7H_2O$	0.3 mg
$MnCl_2$-$4H_2O$	0.35 mg
$FeSO_4$-$7H_2O$	2.5 mg
$CuSO_4$-$5H_2O$	0.5 mg
$MgSO_4$-$7H_2O$	0.5 Gm
Distilled water, to make	1.0 liter
Adjust to pH 5.5 with hydrochloric acid.	
Replacement Medium Medium no. 2	
Citric acid(0.1M)	307.0 ml
Na_2HPO_4-$7H_2O$ (0.2M)	193.0 ml
Distilled water, to make	1 liter
To each replacement culture flask containing 30 ml of this medium (pH 4.2) add 2 mg tryptophan.	

Replacement culture inocula were obtained in a similar manner, but the homogenizing step was extended to one minute. The homogenate from one 125-ml flask was quantitatively transferred to a 2800-ml Fernbach flask containing 300 ml of medium, and mycelium was allowed to develop on a rotary shaker. Mycelial pellets produced in this manner were carefully washed with 500 ml of sterile distilled water; portions were transferred to 125-ml flasks containing 2 mg of tryptophan in 30 ml of medium no. 2 and shaken for the specified period of time.

The shaking machines routinely employed in these studies were a New Brunswick rotary shaker, model V, and a Gump rotary shaker, model M, which were operated at 240 and 185 rpm, respectively.

Analytical methods. - The mycelial pellets, separated from the culture or replacement media by suction filtration on a Büchner funnel, were dried in a forced-air drying oven at 48°C for a minimum period of forty-eight hours and subsequently stored in a desiccator over anhydrous calcium chloride. After determining the pH values of the filtered culture media, the filtrates were evaporated to dryness in a flash evaporator at 40°C under reduced pressure. The residues were carefully extracted with 2-ml portions of absolute methanol to dissolve the psilocybin and psilocin, and the solutions were stored in a refrigerator until subjected to chromatographic analysis.

After drying, the mycelial pellets from the individual culture flasks were weighed and then reduced to a no. 60 powder in a Wiley laboratory mill. Ten ml of methanol was added to each sample (ca. 25-100 mg) of powdered material in a 25-ml flask. After shaking for eight hours, the resulting slurry was centrifuged, and the supernatant liquids decanted into a 50-ml round bottom flask. The marc was treated in an identical manner two additional times, after which the combined methanol extracts were evaporated to a small volume (1-2 ml) in a rotary film evaporator at 40°C under reduced pressure. The concentrated extract was transferred to a 5-ml volumetric flask with a microdropper. Residual material in the evaporation flask was removed by a methanol wash, added to the volumetric flask, and the final volume adjusted to 5 ml. Extracts prepared in this manner were refrigerated until used for assay.

An ascending two-dimensional chromatographic procedure was employed to establish the presence or absence of psilocybin and psilocin. Extracts (50-200 µl) were spotted on sheets of Whatman no. 1 filter paper (8x8 in.) and formed with *n*-butanol-acetic acid water (4:1:5) in the first direction and *n*-propanol-1N ammonium hydroxide (5:1) in the second direction. Location of the indole derivatives was accomplished by spraying the sheets with a solution of 2 percent *p*-dimethylaminobenzaldehyde in 1N hydrochloric acid (PDAB) and drying the sheets with a laboratory heat gun.

Assay procedure. - A paper partition chromatographic assay for psilocybin was developed based on the serial dilution procedure employed by Brown, *et al.*[4], for the assay of muscarine in *Inocybe* species. The technique involved visual observation of the minimum detectable quantity of psilocybin following reaction with PDAB on paper chromatograms. It was determined that 1.0 µg of psilocybin could be detected with certainty on chromatograms developed in *n*-butanol-acetic-acid-water (4:1:5), sprayed with PDAB, and permitted to dry spontaneously at room temperature for thirty minutes. Volumes of mycelial extracts corresponding to this amount of the compound were determined experimentally, and the quantities of psilocybin in the extracts and the mycelium were calculated (dry-weight basis).

Experimental and Results

Growth, pH and psilocybin production. - Cultures employed in the investigation included *Psilocybe cubensis* (Earle) Singer obtained from the Northern Regional Research Laboratory, Peoria, Illinois (NRRL A-9109), *Psilocybe cyanescens* Wakefield and *Psilocybe pelliculosa* (Smith) Singer & Smith, isolated from sporocarp tissue of mushrooms collected in the Seattle area. Mycelium was grown in submerged culture in various media under different laboratory conditions to determine if psilocybin and/or psilocin would be produced. Mycelial pellets of *Psilocybe cubensis* grown in medium no. 1 contained psilocybin, although the culture medium did not; psilocin could not be detected in either the medium or mycelium. The other two species failed to produce detectable amounts of either of these compounds in any of the media tested. It was concluded that the fungi differed in their metabolic capabilities, and, of the three, only *Psilocybe cubensis* was subjected to further investigation.

Initial experiments were conducted to determine the optimal growth period and its relationship to psilocybin production. Cultures of the organism in medium no. 1 were harvested on alternate days, five to fifteen days after inoculation. Replicates of four cultures were examined at each growth period. The pH of the medium at the termination of the experiment, the dry weight of the mycelium, and the amount of psilocybin produced were determined. The results are summarized in table 2 and figure 1.

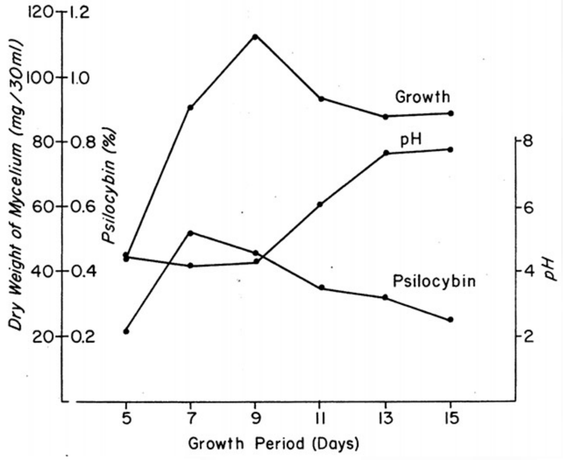

Fig. 1. Growth, pH of medium, and psilocybin production.

These data revealed that the pH of the medium remained acid until the ninth day and then rapidly increased until a plateau was reached near pH 8. Maximum production of psilocybin (percentage basis) occurred on the seventh day, whereas mycelium production reached its peak on the ninth day. Psilocybin was not detected in the medium. Maximum production of both mycelium (dry weight) and psilocybin (percentage basis) occurred in acid medium, and both underwent a decline as the pH of the medium began to rise after the ninth day of fermentation. It was noted that psilocybin was produced during the most active growth period of the organism.

Table 2. Growth, pH of medium, and psilocybin production.

Although psilocybin was initially identified by chromatography, additional evidence was obtained from ultraviolet spectral data. Methanol extracts of mycelium were chromatographed in *n*-butanol saturated with water, the zone corresponding to psilocybin eluted with methanol, and the eluate rechromatographed as before. The ultraviolet absorption spectrum obtained from the final eluate in a Cary spectrophotometer, model 14, was found to coincide with that of known psilocybin (maxima 268 mµ and 290 mµ).

Influence of the omission of certain nutrients. - Subsequent studies were conducted to determine the influence on growth and psilocybin production when each of the following components was omitted singly from medium no. 1: glucose, ammonium succinate, yeast extract, thiamine, and glycine. In a further study, yeast extract and thiamine were concurrently omitted from the medium. Replicates of four cultures for each of the modified combinations, plus control groups, were harvested on the fifth, seventh, and eleventh days after inoculation. Controls were grown in the unmodified medium no. 1. The results are summarized in table 3.

Table 3. Effect of modification of medium on pH, growth, and psilocybin production.

Omission of glucose prevented any appreciable growth of the organism, and detectable quantities of psilocybin were not produced. The absence of yeast extract impaired initial growth; however, the organism adapted to this deficiency and subsequently underwent vigorous growth and comparable psilocybin production. The yield of mycelium in ammonium succinate-free medium was depressed and seven-day-old pellets showed the lowest levels of psilocybin. When glycine was omitted, the amount of psilocybin on a dry weight basis was slightly greater. When yeast extract and thiamine were concurrently omitted, the results paralleled those obtained when yeast extract alone was not included, except that psilocybin accumulation was substantially lower.

Influence of the concentration of certain nutrients. - Experiments were designed to determine the influence of different concentrations of glucose, potassium acid phosphate, and ammonium succinate on the growth and metabolism of the organism. Duplicate cultures containing the following concentrations (percentage basis) of the three individual constituents with normal concentrations of the other ingredients in medium no. 1 were prepared: glucose - 1.0, 0.5, 0.25; potassium acid phosphate - 0.02, 0.01, 0.005; ammonium succinate - 0.2, 0.1, 0.05. These cultures were prepared and processed as previously described. The results are summarized in table 4.

Table 4. Effect of concentration on pH, growth, and psilocybin production.

A low concentration of glucose was associated with a rapid rise in pH, whereas at the high glucose level an acid pH was maintained. Higher levels of glucose resulted in higher yields of psilocybin up to the seventh day, but this may have been due to the increased growth which occurred in this medium. The rapid increase and subsequent decrease of the psilocybin content of mycelial pellets in a medium containing increase glucose is noteworthy. A low phosphate concentration resulted in a rapid decline of the psilocybin level. In this case also, the pH remained acidic through the eleventh day. Variations of the succinate concentration did not influence the organism markedly.

Replacement culture studies. - Since tryptophan had been shown to function as a biosynthetic precursor of psilocybin in surface cultures of *Psilocybe semperviva*, a replacement culture study was designed to determine if mycelium of *Psilocybe cubensis* previously grown in submerged culture could utilize exogenous tryptophan for increased synthesis of psilocybin. This investigation would also provide information regarding the relationship between psilocybin biosynthesis and the growth of the organism.

The replacement culture studies required large quantities of comparable mycelium, and preliminary studies indicated that the metabolism of the organism was markedly influenced by the size of the culture flasks. Mycelial inocula from the source were shaken simultaneously in three Fernbach and three 125-ml Erlenmeyer flasks, and one culture in each size of flask was assayed after seven, nine, and eleven days of incubation, respectively. This comparison indicated that seven-day-old mycelium grown in a Fernbach flask contained an appreciable amount of psilocybin and that the pH of the nutrient broth in the Fernbach flask was still acidic after seven days (Table 5). Thus, the results revealed that seven-day-old mycelium grown in the Fernbach flask had the potential to form psilocybin and was not physiologically old.

Table 5. Comparison between large-scale and small-scale culture of **Psilocybe cubensis**.

Culture flasks (designations)	Age of culture days	pH of medium	Wt of mycelium assayed mg	Psilocybin %
Fernbach	7	4.0	106.8	0.47
Erlenmeyer	7	4.2	43.5	0.46
Fernbach	9	7.1	133.8	0.04
Erlenmeyer	9	4.2	83.1	0.23
Fernbach	11	8.0	159.4	0.03
Erlenmeyer	11	3.8	95.0	0.12

After a small sample of seven-day-old mycelial pellets was withdrawn from the Fernbach flask and tested for the presence of psilocybin, equal portions of the remaining pellets were transferred to twelve replacement culture flasks, each containing 30 ml of medium no 2. Tryptophan (2 mg/flask) was added to half of the replacement cultures, and the remainder served as tryptophan-free controls. Two control cultures and two tryptophan-containing cultures were removed from the shaker and analyzed at 12, 24, and 48 hours, respectively (Table 6).

Table 6. Effect of tryptophan on the biosynthesis of psilocybin in replacement cultures prepared from seven-day-old mycelium.

Cultures	Incubation time hr	Dry wt mycelium mg	Psilocybin (%)
Replacement	12	57.2 42.1	0.24 0.29 ave. 0.26
Control	12	28.1 72.8	0.33 0.24 ave. 0.28
Replacement	24	65.4 66.7	0.18 0.17 ave. 0.17
Control	24	64.9 58.6	0.18 0.14 ave. 0.16
Replacement	48	88.0 91.4	0.12 0.12 ave. 0.12
Control	48	69.1 45.5	0.11 0.18 ave. 0.14

Addition of tryptophan to replacement cultures did not enhance psilocybin production. However, visual comparison of chromatograms revealed that the psilocybin content decreased progressively and that kynurenine accumulation paralleled the decrease in tryptophan content over the forty-eight-hour period.

Discussion

Pellets of *Psilocybe cubensis* produced in medium no. 1 accumulated psilocybin but not psilocin. Maximum production of the former compound occurred on the seventh day (0.52 per cent, dry weight of mycelium), whereas growth attained its maximum (average 112.6 mg, dry weight of mycelium per 30 ml of medium in a 125-ml flask) on the ninth day.

Maximum yields of both psilocybin and mycelium occurred in the acid pH range (4.0-4.6). However, the acidic nature of the medium does not preclude the possibility that the internal pH of the organism is maintained at a different level by an efficient buffering system. Failure to find psilocybin in the medium may be attributed to its instability in the vigorously agitated acid medium, although permeability factors are probably also involved.

In the absence of a readily assimilable carbon source (glucose), detectable amounts of psilocybin did not accumulate. Omission of ammonium succinate did not significantly alter the pH of the medium but it did lower psilocybin yields. Without yeast extract, mycelial production was retarded at five days, and culture liquors remained acidic through the eleventh day. Adaption and/or synthesis of necessary precursors nevertheless permitted a continued increase in growth which was accompanied by a rapid increase in the yield of psilocybin by the seventh day. Similar results were obtained for media from which both yeast extract and thiamine had been omitted, except psilocybin levels remained lower.

According to Cochrane[5] most fungi have an absolute requirement for thiamine; however, where low levels are needed, synthesis takes place after initiation of growth. Under conditions of thiamine deficiency, glucose utilization is impaired, which may account for initial inhibition of growth when yeast extract or that ingredient and thiamine were omitted from the medium. Although glycine constituted more than one-half of the total weight of the dissolved solids in medium no. 1, the organism grew and metabolized efficiently in its absence.

The influence of different concentrations of glucose, ammonium succinate, and potassium acid phosphate in medium no. 1 was noted. A low level of glucose was associated with a rapid rise in extracellular pH, and lower levels of product accumulated. Doubling the normal amount of carbohydrate promoted psilocybin accumulation which reached a level of 1.03 percent (dry weight) by the seventh day. After eleven days, this level dropped to 0.15 per cent; a similar sudden decline in psilocybin content was also noted in those flasks containing a reduced phosphate concentration. The significance of the low pH levels after eleven days is unknown. In contrast, levels of ammonium succinate which were one-half or twice that of the normal medium had no significant effect upon pH or psilocybin production.

Extracellular tryptophan added to replacement flasks did not enhance psilocybin production, but, instead, underwent degradative reactions of the type reported to occur in *Neurospora* and other fungi[5]. This conclusion is based on the observation that a progressive increase in kynurenine, a catabolic product of tryptophan metabolism, paralleled the disappearance of tryptophan. These results are not necessarily contradictory to those obtained by Brack, *et al.*[2], since they used a different organism and different experimental design which preclude a direct comparison. However, our results do establish the existence of a direct relationship between psilocybin production and mycelial growth. Utilization of the replacement culture technique served to separate growth and psilocybin production, whereas the method of Brack, *et al.*, did not afford this distinction. It was concluded that psilocybin production is so intimately related to mycelial proliferation that the nutrient-deficient replacement medium was of little value in the study of psilocybin biosynthesis. However, the technique had previously proven satisfactory for biosynthetic studies of other indole derivatives in fungi[3].

Increasing the scale of fermentation from 30 ml of medium in 125-ml flasks to 300 ml in 2800-ml flasks markedly affected psilocybin production. Significant differences in yields did not appear until after the seventh day when accumulation of product ceased, and a more rapid decline occurred in the large flasks as the pellets became physiologically older. Although the cause of this phenomenon was not established, it may be attributed, at least in part, to differences in the efficiency of aeration of the cultures.

Acknowledgments

This investigation was supported by a PHS research grant (GM-07515-03) from the Division of General Medical Sciences, Public Health Service.

The authors are indebted to Dr. Robert G. Benedict, Department of Pharmacognosy, University of Washington, who provided the original cultures employed in this investigation. They also which to express their thanks to Dr. Alexander H. Smith, University Museums, University of Michigan, Ann Arbor, for providing authoritative identification of the mushroom collections from which the isolates were prepared.

Received 28 May 1963.

Drug Substance and Formulation

Psilocybin (4-phosphoryloxy-*N,N*-dimethyltrypatmine, also referred to as 3-[2- (Dimethylamino)ethyl]-1H-indol-4-ol dihydrogen phosphate ester has the chemical formula $C_{12}H_{17}N_2O_4P$. It is a tryptamine, and is one of the major psychoactive constituents in mushrooms of the Psilocybe genus, as Psilocybe cubensis and Psilocybe mexicanus. Native peoples in Mexico have used the mushrooms in religious ceremonies and in healing (Hofmann 2005). Artifacts and historical documents suggest that ritual use of psilocybin-containing mushrooms occurred as early as 3000 years ago, with documented use occurring in the 16th Century, prior to Spanish prohibition on their use. Psilocybin was first isolated from psilocybe mushrooms by Hofmann in 1957, and later synthesized by him in 1958 (Passie *et al*. 2002). Psilocybin was used in psychiatric and psychological research and in psychotherapy during the early to mid-1960s up until its scheduling in 1970 in the US, and up until the 1980s in Germany (Passie 2005; Passie *et al*. 2002). Research into the effects of psilocybin resumed in the mid-1990s, and it is currently the preferred compound for use in studies of the effects of serotonergic hallucinogens (see for example (Carter *et al*. 2005a; Gouzoulis-Mayfrank *et al*. 1999b; Hasler *et al*. 2004), likely because it has a shorter duration of action and suffers from less notoriety than LSD. However, despite frequent non-medical use in humans, few or no in vitro or nonhuman animal studies with psilocybin have occurred.

Psilocybin belongs to a class of drugs referred to as hallucinogens or psychedelics. Specifically it is a serotonergic hallucinogen, along with other tryptamines such as dimethyltryptamine (DMT), ergolines, such as LSD and phenethylamines, such as mescaline. Currently, research in human and nonhuman animals suggests that serotonergic hallucinogens produce most of their effects as a result of $5HT_{2A}$ agonism, with contributions also from agonism at $5HT_{2C}$ and $5HT_{1A}$ receptors (Nichols 2004). Like other members of this class, psilocybin induces sometimes profound changes in perception, cognition and emotion, including emotional lability.

In humans as well as other mammals, psilocybin is transformed into the active metabolite psilocin, or 4-hydroxy-*N,N*-dimethyltryptamine ($C_{12}H_{16}N_2O$.) It is likely that psilocin partially or wholly produces most of the subjective and physiological effects of psilocybin in humans and nonhuman animals.

Pharmacological and toxicological effects

Psilocybin and Psilocin Actions on Neurotransmitter Systems

Overview

Psilocybin and its metabolite psilocin directly affect a number of serotonin receptors without directly affecting other neurotransmitter systems. While there have been fewer studies of the pharmacological profile of psilocybin than of the ergoline LSD, studies conducted with psilocybin and psilocin indicate that like LSD, these tryptamines are $5HT_{2A}$, $5HT_{2C}$ and $5HT_{1A}$ agonists*. Unlike LSD, they have little affinity for dopamine receptors, and only very high doses affect norepinephrine receptors. Human psilocybin research confirms the $5HT_{2A}$ activity of psilocybin and psilocin, and provides some support for indirect effects on dopamine through $5HT_{2A}$ activity and possible activity at $5HT_{1A}$ receptors.

Psilocybin or psilocin and $5HT_{2A}$ and $5HT_{2C}$ Receptors

A majority of known $5HT_{2A}$ agonists produce hallucinogenic effects in humans, and rodents generalize from one $5HT_{2A}$ agonist to others, as between psilocybin and LSD (Aghajanian and Marek 1999; Nichols and Sanders-Bush 2004). Like lysergic acid diethylamide (LSD) and other serotonergic hallucinogens, psilocybin acts as a serotonin $5HT_{2A}$ receptor agonist (McKenna *et al*. 1990; Nichols 2004). Psilocybin has a stronger affinity for the human $5HT_{2A}$ receptor than for the rat receptor (Gallaher *et al*. 1993), and it has a lower $K_{(i)}$ for both $5HT_{2A}$ and $5HT_{2C}$ receptors than LSD (Nichols 2004). Results from a series of drug-discrimination (DD) studies in rats found that $5HT_{2A}$ antagonists, and not $5HT_{1A}$ antagonists, prevented rats from recognizing psilocybin (Winter *et al*. 2007).

Daily doses of LSD and psilocybin reduced numbers of $5HT_2$ receptors in rat brain (Buckholtz *et al*. 1990). Research examining compound-specific effects on secondary messenger systems found that both psilocybin and LSD stimulate arachidonic acid when activating the rat $5HT_{2A}$ receptor, but psilocybin did not stimulate the phosphoinositide (PI) pathway as strongly as LSD (Kurrasch-Orbaugh *et al*. 2003). However, psilocin stimulated more PI turnover than a ring-fluorinated version of psilocin that rats in DD trials did not consider LSD-like, suggesting that secondary messenger systems might play a role in producing at least some subjective effects (Blair *et al*. 2000). Since investigations of compound-specific or "allosteric" trafficking are new, the functional significance of this difference remains unclear.

Researchers examining psilocybin analogs report that a potential metabolite, 4- methylpsilocin, was a potent $5HT_{2C}$ agonist (Sard *et al*. 2005), but whether or not this compound is produced after psilocybin metabolism is not certain. The development of relatively selective $5HT_{2C}$ antagonists is recent, and to date no studies have examined the contribution of $5\text{-}HT_{2C}$ receptors to the physiological or behavioral effects of psilocybin in human or nonhuman animals.

Psilocybin or Psilocin and other Serotonin Receptors

Direct application of psilocybin to dorsal raphe nucleus (DRN) cells is associated with a decline in firing, a property it shares with LSD (Aghajanian *et al*. 1968; 1970; Aghajanian and Hailgler 1975) that is likely the result of action at $5HT_{1A}$ autoreceptors (Williams *et al*. 1988). In contrast, it appears that $5HT_{1A}$ receptor activity contributes little to the psilocybin stimulus in rats (Winter *et al*. 2007). Though no behavioral studies in humans have determined what role, if any, is played by $5HT_{1A}$ receptors in producing the subjective effects of psilocybin, it is notable that some effects, such as difficulty concentrating, still occur when psilocybin was co-administered along with a $5HT_{2A}$ antagonist (Carter *et al*. 2005a; Carter *et al*. 2005b).

There are no reports describing psilocybin or psilocin actions on $5\text{-}HT_{2B}$ receptors, though the putative psilocybin metabolite *N*-methylpsilocybin was found to act as an inverse agonist at this receptor (Sard *et al*. 2005). However, no studies have as yet detected this metabolite (Hasler 1997; Hasler *et al*. 1997).

McKenna and colleagues reported that psilocybin had an affinity for $5\text{-}HT_{1D}$ receptors as well, possibly explaining its ability to abort cluster headaches (Sewell and Halpern 2006). Beyond this finding, however, there is no published literature that examines the actions of psilocybin or psilocin on $5\text{-}HT_3$ receptors or on any of the more recently discovered receptor families. The ergoline LSD affects a number of these receptors, including 5- HT_{5A} (Nichols *et al*. 2002b), $5\text{-}HT_6$ (Hirst *et al*. 2003) and $5\text{-}HT_7$ (Nichols *et al*. 2002b). However, this does not mean that psilocybin or psilocin possess similar profiles.

Psilocybin or Psilocin and other Receptor Systems

Psilocybin does not act directly on dopamine D_1 or D_2 receptors (Creese *et al*. 1975) or on histamine H_2 receptors (Green *et al*. 1978). Very high doses of psilocybin (25 mg/kg) increased levels of the norepinephrine metabolite 3H-normetanephrine (Stolk *et al*. 1974), but it is unlikely that typical doses of psilocybin used in human research will affect norepinephrine. Because interest in the pharmacology of psilocybin and psilocin declined prior to the development of modern neuropharmacology, the complete pharmacological profile of either compound is not as well-known as that of LSD. It is possible that psilocybin, like LSD, acts on one or more of the more recently discovered serotonin receptors, such as $5\text{-}HT_{5A}$ or $5\text{-}HT_7$, but currently there is no information on the actions of psilocybin at these receptors. It is likely that psilocybin itself, or its metabolite psilocin, aborts cluster attacks through its effects on $5HT_{1D}$ receptors.

One team of researchers performed a series of experiments, many comparing LSD with the non-hallucinogenic compound lisuride and using a mouse model of hallucinogen-associated behavior (head twitch), suggesting that stimulating different secondary messenger systems may play a role in hallucinogenic effects (Gonzalez-Maeso *et al*. 2007). Instead of activating only phospholipase C (PLC) when stimulating $5HT_{2A}$ receptors, LSD and the phenethylamine DOI stimulated pertussis-toxin sensitive $G_{i/o}$ proteins. It is not yet known whether psilocybin shares this feature with LSD and DOI.

Table 1 Psilocybin Binding Data

Human Neuropharmacological Studies

In studies in humans, researchers found that administering psilocybin along with a 5HT$_{2A}$ receptor antagonist, such as ketanserin or risperidone, attenuated or completely abolished the subjective and perceptual effects of psilocybin (Carter *et al*. 2004; Vollenweider *et al*. 1998). Ketanserin did not attenuate reduced visual attention or psilocybin-associated changes in binocular rivalry (oscillation in dominance of one eye over another in visual perception) (Carter *et al*. 2005a; Carter *et al*. 2004). Coadministration of the dopamine D$_2$ receptor antagonist haloperidol only reduced positive mood and positively viewed changes in cognition and perception Vollenweider *et al*. 1998. A human imaging study using radiolabeled raclopride, a D$_2$ receptor antagonist found reduced binding in caudate and putamen after psilocybin administration, suggesting that psilocybin indirectly increased brain dopamine levels, (Vollenweider *et al*. 1999) probably through 5HT$_{2A}$ activity. Taken together, these findings suggest that psilocybin produces its effects in humans chiefly but not wholly through 5HT$_{2A}$ receptors, while the compound may produce different effects through other serotonin receptors, such as 5HT$_{1A}$ or 5HT$_{2C}$. Psilocybin may exert indirect influence over the dopamine system without having any direct effects on dopamine receptors.

Psilocybin and Gene Expression

When activating 5HT$_{2A}$ receptors, psilocybin and LSD both increase expression of a number of genes, including *egr-1*, *egr-2*, *period1*, *Nor1* and *l-KappaBetaAlpha* (Gonzalez-Maeso *et al*. 2003; Nichols and Sanders-Bush 2002). Psilocybin may be associated with a greater increase in egr-1. The significance of psilocybin effects on gene expression is uncertain. However, changes in gene expression may play a role in the ability of psilocybin-containing mushrooms to interrupt cycles of cluster headache, or cluster headache period, as discussed below in "Safety and Toxicity" (Sewell *et al*. 2006).

Physiological and Psychological (Subjective) Effects

Studies in humans and nonhuman animals indicate that (Winter *et al*. 2007) psilocybin has extremely low toxicity (Nichols *et al*. 2002a; Passie *et al*. 2002). LD$_{50}$ ranged from 285 mg/kg in rats and mice to 12.5 mg/kg in rabbits (Usdin and Efron 1972). It is likely that the lethal dose in humans far exceeds doses that produce profound alterations in consciousness. All ongoing and proposed research will use doses of approximately 0.4 mg/kg, which is at least 20 times smaller than the LD$_{50}$ in rabbits.

Psilocybin Effects in Nonhuman Animals

Rats trained to distinguish between LSD and saline injections treated psilocybin as if it were LSD (Koerner and Appel 1982; Schechter and Rosecrans 1972), suggesting that the two drugs possess similar stimulus characteristics, a finding supported in early human studies comparing the two compounds (Hollister and Hartman 1962; Hollister and Sjoberg 1964; Isbell 1959; Wolbach *et al*. 1962). Rats trained to recognize psilocybin identified psilocin as psilocybin-like, indicating that psilocybin and its metabolite produce similar cues in these animals. As described later on in this document, most psilocybin is converted into psilocin, and it is likely that most of the physiological and subjective effects of psilocybin are in fact due to psilocin.

Researchers examined the effects of psilocybin in rats, cats, dogs and rabbits found that psilocybin produced piloerection, slight increases in breathing, indications of sympathetic system stimulation, but no increase in locomotor activity (Maxwell *et al*. 1962; Passie *et al*. 2002), Psilocybin increased prolactin levels in rats (Meltzer *et al*. 1978). As described above, behavioral reports of the effects of psilocybin demonstrated that psilocybin produced effects similar to LSD or other tryptamines. As with the ergoline LSD, psilocybin reduced and altered rat exploratory patterns (Geyer *et al*. 1978). Monkeys self-administering psilocybin exhibited behavior suggestive of visual distortions or alterations in consciousness that included grasping at unseen objects and fixed staring (Fantegrossi *et al*. 2004), behaviors also seen when the animals self-administered DMT or mescaline. There is no indication that psilocybin produced unique physiological or behavioral effects in rodents or nonhuman primates.

Psilocybin Effects Assessed in Humans

Hasler and colleagues report that the first or onset effects of orally administered psilocybin appeared approximately 20 to 30 minutes post-administration (Hasler *et al*. 1997; Hasler *et al*. 2004), and peak effects appeared 60 to 90 minutes post-drug. The effects of orally administered psilocybin subsided four to six hours after drug administration (Hasler *et al*. 2004). Changes in perception and cognition were no longer detectable seven days later (Gouzoulis-Mayfrank *et al*. 1999b). Onset of 1 mg intravenous psilocybin effects appeared 2 minutes after administration, with subjective and physiological effects lasting for up to 20 minutes afterwards (Hasler *et al*. 1997). Isbell detected increased pupillary diameter after approximately 4, 6 and 8 mg psilocybin and elevated systolic blood pressure after approximately 6 mg psilocybin (Isbell 1959), and later reports also detected elevations in blood pressure and heart rate after higher doses of psilocybin (Griffiths *et al*. 2006; Hasler *et al*. 2004), though sometimes changes were only detected at one point in time, as 60 minutes post drug (Hasler *et al*. 2004). Hence psilocybin produces only slight sympathetic system activation. It is notable, however, that a 26-year old man with obsessive compulsive disorder (OCD) exhibited an elevation in diastolic blood pressure from 91 to 104 mm Hg after receiving 0.2 mg/kg psilocybin in the absence of self-reported anxiety (Moreno *et al*. 2006). Psilocybin elevated prolactin, but not cortisol or ACTH (Gouzoulis-Mayfrank *et al*. 1999b; Hasler *et al*. 2004), with prolactin elevation no longer detectable 300 minutes (5 hours) post-drug (Hasler *et al*. 2004). In general, physiological effects are similar to those of the ergoline hallucinogen LSD. To date, there are no findings that either support or disconfirm the existence of menstrual variations in the effects of psilocybin in women.

Psychological and Subjective Effects

Early studies of psilocybin in humans reported changes in perception, as increased perception of visual after-image (Keeler 1965), peculiar thoughts, anxiety, and unusual experiences of the body (as parasthesias) and the environment (Fischer *et al*. 1966; Hebbard and Fischer 1966; Hofmann *et al*. 1958; Hollister and Sjoberg 1964; Isbell 1959; Keeler 1963), and side effects of dizziness, impaired concentration and nervousness (Hollister and Sjoberg 1964). Some early reports also found increased difficulty in performing some tasks, such as simple arithmetic problems (Hollister 1961). Psilocybin elicited spiritual or mystical experiences in divinity students during a religions service (Pahnke 1963). This study employed a placebo, but the researchers administered psilocybin or placebo to groups of participants, and retrospective reports suggest that participants could accurately guess their condition from observing themselves or others (Doblin 1991). Recent studies confirmed initial findings (Carter *et al*. 2005a; Carter *et al*. 2004; Gouzoulis-Mayfrank *et al*. 1999b; Griffiths *et al*. 2006; Hasler *et al*. 2004; Vollenweider *et al*. 1997). Participants reported alterations in perception (Gouzoulis- Mayfrank *et al*. 1999b; Griffiths *et al*. 2006; Hasler *et al*. 2004; Vollenweider *et al*. 1997), and assessments of visual perception detected changes in motion perception, binocular rivalry and time perception (Carter *et al*. 2004; Carter *et al*. 2005b; Wittmann *et al*. 2006). A study of the effects of psilocybin in pre-pulse inhibition (PPI), the reduction in startle response to an intense stimulus if preceded by a less intense stimulus, reported enhanced PPI after a long interval between pre-pulse and pulse, and attenuated PPI when the interval was short (Vollenweider *et al*. 2007). Participants experienced both increased positive mood and positively experienced derealization (feeling as if they were "in a dream" or as if the external world were unreal) and depersonalization (sense of "being unreal," or of the self belonging to someone else) and negative mood and negatively experienced derealization and depersonalization. Mood could change rapidly over time from very positive to very negative (Vollenweider *et al*. 1997). Psilocybin was far more likely than methylphenidate to produce mystical or peak experiences in people with existing religious or spiritual practices (Griffiths *et al*. 2006). People receiving psilocybin in these studies maintained insight concerning the source of their alterations in perception. Observers' descriptions of participant behavior were consistent with the participants' accounts, noting mood lability, changes in sense of self, and unusual or paranoid thoughts (Gouzoulis-Mayfrank *et al*. 1999b; Griffiths *et al*. 2006; Vollenweider *et al*. 1997).

Factors influencing psychological reactions to psilocybin

The variable subjective effects of psilocybin are due at least in part to differences in preexisting mental state and personality, or "set" and to features of the immediate environment, or "setting" (Nichols 2004). In an early investigation summarizing findings from uncontrolled studies of psilocybin, Leary and colleagues reported that people reporting previous experience with psychoactives, greater feelings of flexibility and lower apprehension about taking psilocybin had more pleasant experiences with psilocybin (Leary *et al*. 1963). The same report also indicates that features of setting, such as administration in small groups, were associated with more pleasant experiences than when administered in larger groups. Therapists describing their use of LSD or other psychedelics in therapy (Grof 2000: 1980) favored comfortable settings. Patients remain within the confines of the setting during therapy, and sometimes use eyeshades and listen to music to foster introspection and reduce distraction. There has been little formal investigation into the impact of set and setting, but there is at least informal evidence that both may play a role in response to psilocybin.

Long-Term Effects of Psilocybin

To date, only Griffiths and colleagues have assessed potential long-term changes after psilocybin in the context of a double-blind, active placebo controlled study, finding that two months after drug administration, participants were more likely to report positive attitudes toward life and the world and increased satisfaction and well-being after psilocybin than after methylphenidate, and friends noticed small positive life changes after psilocybin (Griffiths *et al*. 2006). Neither psilocybin nor methylphenidate produced negative changes in attitudes or life changes. Interviews and questionnaires occurring approximately 25 years after the study of the effects of psilocybin in divinity students observing a religious service found that participants who had received psilocybin continued to report a greater number of positive life changes than controls, and very few negative life changes (Doblin 1991). As described earlier, groups of participants underwent the study and the blind was poorly maintained, but follow-up interviews suggest that the lasting effects of psilocybin are positive.

Psilocybin/Psilocin Effects on Brain Activity

Positron emission tomography (PET) studies of psilocybin in humans have detected increased glucose metabolism in frontal areas and anterior cingulate, with possibly greater right hemisphere activity (Gouzoulis-Mayfrank *et al*. 1999a; Vollenweider *et al*. 1997). However, an imaging study using radiolabeled raclopride (a D_2 antagonist), described above, did not find lateral effects in changes in D_2 binding (Vollenweider *et al*. 1999). Since changes in glucose metabolism can arise from direct and indirect brain activity, and can be indicative of inhibitory or excitatory actions, it is difficult to draw conclusions from these studies alone. However, they suggest that at least some of the effects of psilocybin result from changes in frontal or cingulate activity.

Pharmacokinetics and biological disposition of the drug

Psilocybin is detectable in plasma 20 to 40 minutes after oral administration (Hasler 1997) reviewed in (Passie *et al*. 2002). Psilocybin is metabolized in the liver, where it is chiefly transformed into the active metabolite psilocin, detectable in plasma 30 minutes after administration (Hasler 1997; Hasler *et al*. 1997; Lindenblatt *et al*. 1998; Passie *et al*. 2002), with psilocin first appearing in plasma 15 to 50 minutes after oral administration of 0.2 mg/kg psilocybin. Psilocin half-life ranges between 2 and 3 hours, and is detectable 6 hours after oral administration (Hasler *et al*. 1997; Lindenblatt *et al*. 1998). These two studies reported similar but not identical findings, with peak levels of psilocin appearing between 80 and 105 minutes and psilocin half-life ranging between 2.25 h for 0.2 mg/kg and 2.7 h for 0.22 mg/kg.

Hasler and colleagues have detected three additional psilocybin metabolites; 4-hydroxy- 3-yl-acetaldehyde (4HIA), 4-hydroxy-3-yl-acetic acid (4HIAA), and 4-hydroxytryptophol (4I-IT) (Hasler 1997).

Figure 1: Metabolism of psilocybin; from Hasler 1997 and reproduced in Passie et al. 2002.

Previous research in non-human animals found that the phosphoric ester group of psilocybin is cleaved by alkaline phosphatase (Horita and Weber 1961; 1962). Rat intestinal tissue readily took up psilocin, but not psilocybin, and the tissue transferred psilocin into blood side solutions (Eivindvik *et al*. 1989), suggesting that psilocin is also more readily distributed around the body than any unmetabolized psilocybin. While there are currently no studies of psilocin metabolism, psilocin is likely metabolized by deamination and demethylation via liver enzymes such as monoamine oxidase and aldehyde dehydrogenase (Hasler *et al*. 1997).

Psilocin and psilocybin are eliminated through the kidneys, both as unaltered drug and conjugated with glucuronides (Hasler *et al*. 2002), with most psilocin and psilocybin excreted three hours after oral administration. Researchers detected inter-individual variation in urinary excretion of psilocin and psilocybin. Most detectable psilocin appeared between two and four hours after drug administration. On the basis of urinary psilocin levels 12 to 24 hours after approximately 0.21 mg/kg psilocybin, it is likely that most or all psilocybin and psilocin is excreted from the body at or within 24 hours after administration (Hasler *et al*. 2002).

Safety and effectiveness in humans obtained from prior clinical studies

History of Psychiatric Research with Psilocybin

At least 19 studies have described the psychotherapeutic potential of psilocybin in approximately 1960 participants (as summarized in (Passie 2005)). These studies employed an average minimum dose of 8.24 mg (0.118 mg/kg) and an average maximum dose of 17.19 mg (0.246 mg/kg). Most psychotherapists and psychiatric researchers who performed psilocybin-assisted psychotherapy wished to activate an individual's unconscious memories and conflicts, and chose doses that produced this effect (see for example (Hausner and Dolezal 1963; Leary *et al*. 1963; Leuner 1963)). The researchers probably used processes similar to those described for LSD-assisted psychotherapy (Grof 2000: 1980; Grof *et al*. 1973; Kurland *et al*. 1967). Psilocybin-assisted therapy either followed the psycholytic model or the psychedelic model. Psycholytic psychotherapy involved lower doses of a psychedelic compound and more interpretation and analysis during the session, while psychedelic psychotherapy employed higher doses, with interpretation occurring after the experience (Passie 2005). Previous research has also examined the capacity of psilocybin to induce mystical or spiritual experiences in people during a structured religious service (Pahnke 1963; Pahnke and Richards 1966), a finding followed by recent studies of spiritual or peak effects in people with religious or spiritual practices (Griffiths *et al*. 2006).

Recently, several investigators have examined or are in the process of examining psilocybin as a treatment for specific mental and neurological disorders. These include anxiety arising from diagnosis with advanced stage cancer, interruption of cluster headache cycles or periods, and treatment of obsessive-compulsive disorder (OCD). Results for the investigation of psilocybin in people with OCD are now published, while studies of advanced-stage cancer are still underway. A study of psilocybin in people with cluster headaches is planned and has not yet occurred.

Psilocybin in People with Advanced Stage Cancer

Following previous research indicating that LSD-assisted psychotherapy reduced anxiety and improved quality of life in people with advanced stage illness (Grof *et al*. 1973), Grob and colleagues decided to investigate the effects of psilocybin-assisted psychotherapy in this population. Research is currently underway looking into the effects of psilocybin-assisted psychotherapy in people with anxiety related to diagnosis with advanced stage cancer and a projected life expectancy of less than a year (Grob 2005). This study intends to enroll twelve participants. Ten participants have been enrolled in this study. Psilocybin has so far been well-tolerated in this sample and there have been no reports of drug-related serious adverse events.

Psilocybin as Potential Treatment of Cluster Headaches

Cluster headache (CH) is a debilitating illness affecting approximately 250,000 people in the United States. CH attacks are characterized by periods of excruciating pain in the temple, eye, or jaw that can last for up to 90 minutes. Cluster attacks tend to occur during specific times of day, and they can occur during specific times of year. While medications exist that abort cluster headaches, there are no medications that interrupt cluster headache cycles, or periods. Recently, Sewell and colleagues published a case series of 53 people who had self-administered psilocybin-containing mushrooms ("magic mushrooms") or LSD as a means to treat cluster headache (Sewell *et al*. 2006). Twenty-five of 48 respondents who used psilocybin-containing mushrooms reported that they had terminated their cluster period, and 18 respondents (37%) reported that psilocybin was partially effective in reducing attacks during cluster periods. Subsequent to these reports, at least one team of researchers plans to conduct a controlled study of the safety and efficacy of psilocybin in the treatment of CH, focusing on interruption of cluster headache period.

Psilocybin in People with OCD

Several published case reports have suggested that people could gain symptomatic relief from OCD through ingesting psilocybin-containing mushrooms or LSD (Hanes 1996; Leonard and Rapoport 1987; Moreno and Delgado 1997). On the basis of these accounts, Moreno and colleagues conducted a randomized, double-blind dose-response investigation of psilocybin in nine participants with OCD. They reported that up to 300 mcg/kg psilocybin was well-tolerated and that all participants exhibited at least transient reduction in symptoms, assessed via Yale-Brown Obsessive Compulsive Scale (Y-BOCS). Psilocybin attenuated OCD symptoms even after doses as low as 25 mcg/kg (Moreno *et al*. 2006), raising questions as to interpreting results with respect to whether the lowest dose served as a placebo and whether it was in fact devoid of therapeutic effects. One participant in this study remained symptom-free five months later.

Possible risks and side effects

Overview of risks

Psilocybin is not associated with disease to any organ or system (Nichols 2004 see also IND # 56,530, submitted by Francisco Moreno). Searches of publicly available databases of medical publications have failed to find any cases of psilocybin causing any serious illness to any organ or system. A recent extensive search conducted on the PubMed database in September, 2005 using the words "psilocybin" and various organs or medical terms ("heart," "cardiac," "liver") and "adverse event" uncovered only a single case of liver problems. An additional search using the word "psilocybin" alone conducted on August, 2006 also failed to turn up any new cases of adverse events after psilocybin. More commonly, damage or disease to organs (as renal failure) is associated with mistakenly consuming poisonous mushrooms under the belief that they are psilocybin-containing varieties (see for example (Franz *et al*. 1996)). Research using radiolabeled psilocybin found it evenly distributed throughout the body (Passie *et al*. 2002). People in Mexico have likely used psilocybin-containing mushrooms for at last hundreds and possibly thousands of years (Hofmann 2005), and research with psilocybin began soon after its isolation and synthesis. A lack of case reports of physical illness or disease arising from exposure to psilocybin despite the long history of use within and outside of research settings is encouraging and indicative of association with few risks outside of the well-known psychiatric and psychological adverse events (described below). The low rate of serious adverse events and lack of fatalities is especially notable.

Approximately 2000 people have received psilocybin during the course of initial psychological and psychiatric investigations of psilocybin (Metzner 2005), and psilocybin has since been administered to over 216 participants during the current wave of neuroscience and psychiatric research. As was true in the case of previous human psilocybin studies described above, no serious adverse events have occurred during recently published research studies (Carter *et al*. 2005a; Carter *et al*. 2005b; Gallaher *et al*. 1993; Gouzoulis-Mayfrank *et al*. 1998; Gouzoulis-Mayfrank *et al*. 2002; Griffiths *et al*. 2006; Hasler *et al*. 1997; Hasler *et al*. 2002; Hasler *et al*. 2004; Lindenblatt *et al*. 1998; Spitzer *et al*. 1996; Umbricht *et al*. 2003; Vollenweider *et al*. 1997; Vollenweider *et al*. 1998; Vollenweider *et al*. 1999; Wittmann *et al*. 2006). Drug-naïve participants can safely receive intensely e doses of psilocybin if prepared for the effects (Griffiths *et al*. 2006). Hasler and colleagues halted administration of 3 mg i.v. because participants reported a greater number of side effects and reported finding the subjective effects 3 mg i.v. too intense and frightening (Hasler *et al*. 1997).

Fatalities

To date, there have been no verified fatalities directly due to ingesting psilocybin or mushrooms containing only psilocybin and related compounds. When reported, it is likely that fatalities attributed to psilocybin-containing mushrooms are due instead to unintended consumption of poisonous mushrooms in the belief that they contain psilocybin. Extremely high doses of psilocybin might induce effects similar to extremely high doses of LSD, such as fever or respiratory failure (Klock 1978). However, to date no cases have described similar responses with respect to psilocybin, and the doses of psilocybin that might provoke these physiological effects would be many times greater than even the highest doses used in early human studies.

Common Adverse Events and Side Effects

Common adverse effects of psilocybin are described above in "Physiological Effects" and "Psychological Effects" above. They include altered perception of time and space, anxiety, derealization (feeling as if the world is "unreal" or that one is "in a dream), depersonalization (feeling as if the self is unreal or belongs to "someone else"), experiencing both positive and negative moods and mood lability (given to rapid and sometimes intense changes), dilated pupils, dizziness, feeling dazed or fatigued, impaired concentration, unusual body sensations, sporadic, transient increases in blood pressure or heart rate, labile (extremely changeable) mood, nausea, nervousness, unusual body sensations, unusual thoughts, and yawning. Most of these effects are acute and last no longer than the four to six-hour duration of drug effects (Gouzoulis-Mayfrank *et al*. 1999b; Hasler *et al*. 2004; Hollister 1961; Passie *et al*. 2002; Vollenweider *et al*. 1998; Wittmann *et al*. 2006).

The adverse effects of psilocybin are all psychological and similar to those reported for the ergoline hallucinogen LSD, and include anxiety or panic response, a prolonged unpleasant experience (or "bad trip"), psychotic reactions, and prolonged perceptual disturbances. Psychological distress is the chief adverse event reported in the literature on the recreational or nonmedical use of psilocybin, which includes extreme anxiety or panic reactions or transient psychosis (Peden and Pringle 1982).

Reckless Behavior

As is true of LSD and other serotonergic hallucinogens, people who have taken psilocybin in uncontrolled settings may engage in reckless behavior, such as driving while intoxicated. Participants in this and all foreseeable studies will remain in a controlled setting throughout the duration of the subjective effects of psilocybin, and in many studies, they will remain at the setting overnight. Thus it will be extremely unlikely that participants will perform high-risk behaviors, including driving motor vehicles, during the period of intoxication.

Anxiety and Panic Response

Reports specific to consumption of psychedelic mushrooms (Hyde *et al*. 1978; Musha *et al*. 1986; Peden and Pringle 1982) report the occurrence of usually transient anxiety or psychosis-like symptoms similar to those reported for LSD (Strassman 1984). A survey of 44 individuals admitted to hospital after psilocybin use reported the most common adverse event to be dysphoria that lasting for an average of 3.8 hours, followed by nausea or vomiting in at least half the admissions (Peden and Pringle 1982). As might be expected after compounds known to alter perception (Nichols 2004; see "Previous Human Experience" below), people in this study also reported alterations in perception and parasthesias (unusual body sensations, such as numbness or tingling). These reactions typically resolved spontaneously with supportive care, or, on some occasions, with the use of sedative medications such as benzodiazepines. In most cases, emergency room admissions related to anxiety or psychological distress after psilocybin does not require hospitalization (Strassman *et al*. 1994). The occurrence and intensity of anxiety or panic responses to psilocybin can be reduced through informing participants about drug effects prior to drug administration, supervision and monitoring participants throughout the duration of drug effects by people trained to deal with panic or anxiety, including anxiety in response to hallucinogen effects, and exposure to lower doses before receiving higher doses.

Transient and Prolonged Psychotic Reaction

Some individuals enter transient and sometimes prolonged psychotic states after use of psychedelics, including psilocybin (Benjamin 1979; Halpern and Pope 1999; Strassman 1984). Because in nearly all cases, psychosis appears after use without evaluation of psychological state prior to psilocybin use, drawing conclusions about causality is difficult. After examining the literature, Strassman concluded that hallucinogens, including psilocybin, might trigger psychotic episodes, but in a non-specific and non-etiologic manner, and that they did not cause psychosis in people (Strassman 1984). Researchers examining the prevalence of psychiatric reactions through questionnaires sent to researchers conducting controlled studies with the related serotonergic hallucinogen LSD found that 0.08% of 5000 study volunteers experienced psychiatric symptoms that lasted more than two days (Cohen 1960). The rate of occurrence for psychiatric symptoms occurred at the slightly higher rate of 0.18% in psychiatric patients. Another survey of a separate sample of 4300 research volunteers reported a rate of serious, persistent psychiatric reactions in 0.9% of the sample (Malleson 1971). Psilocybin and LSD produce similar subjective effects. Hence these findings suggest that participating in a research study involving the administration of a psychedelic compound similar to LSD is extremely unlikely to trigger transient or persistent psychosis. Past research with LSD and other psychedelics did not apply as stringent criteria for participant selection or screening as are used today, making the low rates of psychosis especially notable (Halpern and Pope 1999), and likely overestimates the likelihood of prolonged psychoses or other psychopathological effects in a study wherein participants are screened for past or present psychotic disorders. The occurrence of transient or persistent psychosis can be prevented or further reduced by excluding people on the basis of the presence of past or current psychotic disorders or such disorders in first-degree relatives, such as biological parent or sibling.

Post-Hallucinogen Perception Disorder (HPPD)

Some people who have used serotonergic hallucinogens, such as LSD or psilocybin, experience persistent, distressing alterations in mostly visual perception that last from weeks to years after use. This condition is now diagnosed as hallucinogen persistent perception disorder (HPPD), and is no longer referred to by the term "flashbacks," which better describe an experience more akin to traumatic recall of an intensely upsetting experience, as a "bad trip." HPPD has occurred after use of psilocybin-containing mushrooms (Benjamin 1979; Espiard *et al*. 2005). To date, there are no reports describing prevalence of HPPD in the general population, but an examination of previous reports and estimates of psychedelic use in the US suggests that HPPD is very rare (Halpern and Pope 2003; Johnston 2005). Halpern and Pope noted that many to most previous studies were affected by selection bias. These reports also contained information supporting alternative explanations of flashbacks or HPPD, such as use of other drugs or the presence of other mental disorders, and found that people who had not used hallucinogens sometimes also reported experiencing similar perceptual disturbances. As well, preliminary data collected by Baggott suggests that no more than 1% of hallucinogen users experience HPPD [Baggott 2006; personal communication to L Jerome]. To date, no cases of HPPD have occurred in volunteers given psilocybin in current research studies. The risk of HPPD occurring after psilocybin administration can be reduced by screening participants for potential risk factors such as substance dependence and through excluding people reporting HPPD after prior use of hallucinogens.

Long-Term Personality Changes after Psilocybin

Though the possibility of chronic neuropsychological effects have never been specifically addressed with respect to psilocybin, earlier studies reported detecting changes in personality or neuropsychological function in people reporting frequent or chronic use of LSD, as described in a review by Halpern and Pope (1999). However, later examinations of these studies found that they possessed a number of methodological flaws, including retrospective study design and failure to account for use of other drugs. Halpern and Pope concluded that long-term changes in personality or psychological function after LSD, if they occurred at all, were liable to be subtle and not clinically significant. Psilocybin shares pharmacological mechanisms with LSD, and so these results seem likely to be applicable for this compound as well. Furthermore, a study of the ability of approximately 0.43 mg/kg psilocybin to produce spiritual experiences found that participants reported an increase in positive attitude changes and behavior two months after psilocybin administration, and people who knew these participants concurred (Griffiths *et al*. 2006). Monitoring personality before and after psilocybin administration will allow researchers to detect personality changes.

Abuse Potential

Currently, psilocybin is placed in Schedule 1, defined as having no medical use and possessing high abuse liability. Despite this designation, examining use patterns in humans and studies in nonhuman primates suggest that psilocybin possesses little or no abuse liability. Monkeys in a study of the rewarding properties of four serotonergic compounds found that the animals did not consistently self-administer psilocybin (Fantegrossi *et al*. 2004). It is also notable that rhesus monkeys found LSD, a drug with similar pharmacological and subjective effects, to be aversive (Hoffmeister 1975). There is no human dependence syndrome for LSD, a drug sharing some similarities with psilocybin, and prevalence of LSD use in adolescents and young adults seems to remain relatively stable over time in the US (Johnston *et al*. 2005). It seems likely that psilocybin also has the same low abuse liability described for LSD. Surveys of drug use in the US do not even ask specifically about use of psilocybin-containing mushrooms, suggesting that use of these mushrooms is relatively uncommon. While very few studies specifically ask respondents about use of "magic mushrooms," there appears to be little notable change in prevalence of "hallucinogen" use in adults aged 19 to 28 (Johnston and O'Malley 2004), with 19.6% reporting some use in 2002 and 20% in 2003. A survey of national drug use in Canada also indicated that hallucinogens accounted for very few admissions for substance abuse (Poulin *et al*. 1999). It is not expected that either psilocybin-naïve or experienced individuals will develop dependence after exposure, even if exposure may lead to pain reduction, as it may in the case of people with cluster headaches.

Reproductive Toxicity

There have been no systematic examinations of the effects of psilocybin in utero. Previous research with LSD had first detected chromosomal abnormalities, but subsequent research failed to detect any abnormalities (Cohen and Shiloh 1977; Cohen 1967; Dishotsky *et al*. 1971). Psilocybin did not produce any indicators of mutagenicity in the micronucleus model of mutagenicity (Van Went 1978). These findings suggest that psilocybin is unlikely to damage DNA. Furthermore, there do not appear to be any case reports of birth defects arising from psilocybin use. Nevertheless, the reproductive risks of psilocybin, though likely minimal, remain unknown. Reproductive risks can be prevented or eliminated through restricting enrollment to women who are not pregnant or lactating and who are using an effective means of birth control.

Trial Data

There are no ongoing sponsor-supported trials of psilocybin at present. In future, data will be collected and reported on psilocybin side effects.

Acknowledgements

I would like to thank Torsten Passie MD for sharing information from his review of the literature, Felix Hasler for permission to reproduce the figure describing the metabolism of psilocybin from his dissertation, Andrew Sewell for continued discussions of the effects of changes in gene expression in relation to psilocybin and other 5-HT$_{2A}$ agonists, and any of the people who devoted some time and effort to reviewing the document and providing me with helpful comments and advice.

A number of indolic compounds have gained pharmacological and biochemical interest because of their ability to produce psychotic states in human subjects. Thus, compounds such as bufotenin, *N,N*-dimethyl-tryptamine and harmine (1) have been reported to produce behavioural changes in man and various central nervous system effects in experimental animals. The most recent additions to this class of compounds are the substances found in the *Psilocybe mexicana* Heim mushroom, psilocybin and psilocin. Chemically, these compounds are 4-phosphoryl-*N,N*-dimethyltryptamine and 4-hydroxy-*N,N*-dimethyltryptamine, respectively. Their chemical structures are shown below.

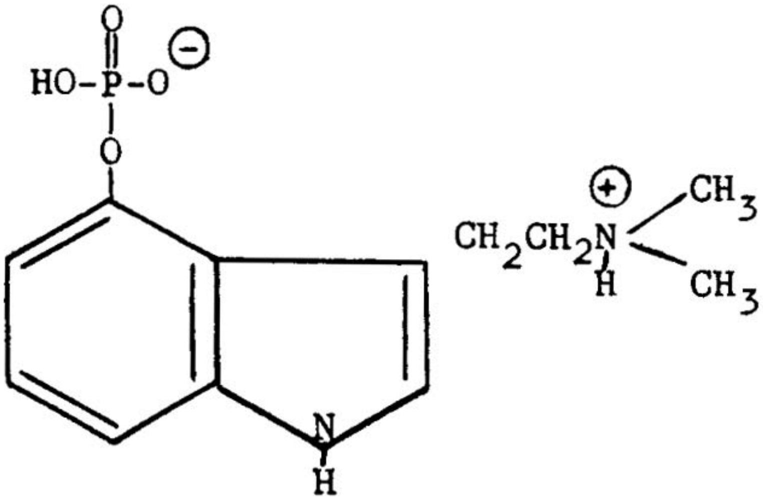
According to Troxler *et al*. (2) psilocybin and psilocin are the first indole compounds of natural sources possessing substitutions on the 4-position of the indole ring. Psilocin differs from bufotenin only by having its -OH group located on the 4- rather than the 5-position.

The present report is concerned with hydrolysis of the phosphate group of psilocybin *in vitro* by a purified preparation of calf intestinal phosphatase. These studies were initiated because of the possibility that psilocybin might serve as a substrate for the phosphatase enzyme. This appeared reasonable since other aromatic compounds with a phosphate group are excellent substrates of acid and alkaline phosphatases (3).

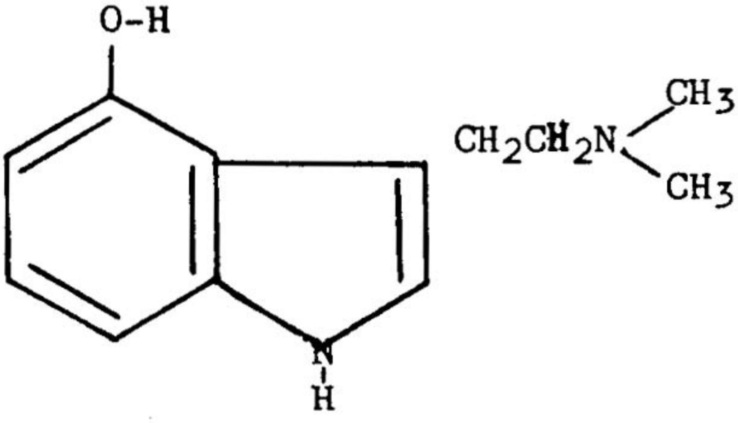
Methods

All experiments in this study were carried out using purified calf intestinal phosphatase containing 15,000 units per mg (Purified alkaline phosphatase preparation was purchased from Mann Research Labs., New York.). Psilocybin and psilocin were generously supplied by Mr. Harry Althouse of Sandoz Pharmaceuticals, San Francisco, Calif.

Inorganic phosphate was determined according to a modified method of Fiske and Subbarrow (4). Psilocin was determined by adapting the colorimetric analysis for serotonin as described by Udenfriend *et al*. (5). All steps in the procedure were similar to that for serotonin. The final reaction between the nitrosonaphthol reagent and psilocin in an acid medium resulted in formation of a brownish-orange color as compared to the bright violet color of serotonin or bufotenin. The color with psilocin exhibited maximum absorption at wave lengths of 540 and at 430 mμ as read on the spectrophotometer. Determinations of psilocin were made at 430 mμ, although in some instances they were also checked at 540 mμ. Colors developed from standard solutions of pure psilocin were found to follow Beer's Law within the concentration range of 0.02 and 1.0 μmoles/ml.



Psilocybin



Psilocin

Psilocybin also reacted with the nitrosonaphthol reagent but only at much higher concentrations. It exhibited a light yellow color, but this did not interfere with the psilocin readings at 430 mμ. Psilocybin, however, is not extracted into the butanol phase, and the final acid extract did not give any color reaction with the nitrosonaphthol reagent. This permits a selective extraction of psilocin by the butanol and prevents interference by any psilocybin that might be present.

The incubation mixture consisted of the following: 0.4 ml of intestinal phosphatase (1500 units/ml) and 5.0 ml of psilocybin (2 μmoles/ml) dissolved in Veronal buffer (pH 9.2). The psilocybin was pre-incubated for 5 minutes in order to equilibrate to 37°C. The enzyme solution was then added, and at varying times, tubes were removed and assayed for psilocin and inorganic phosphate. Duplicate assays were performed for each tube.

Descending paper chromatography of the incubation mixtures was used as a further identification of psilocin. A butanol-acetic acid-water (4:1:1) mixture acted as the developing solvent, and the spots were detected with a cinnamaldehyde-HCl reagent (6).

Results

The ability of purified intestinal alkaline phosphatase to dephosphorylate psilocybin with liberation of psilocin and inorganic phosphate is illustrated graphically in Fig. 1. A rapid dephosphorylation is evident in the initial 15-30 minutes and thereafter proceeds at a slower linear rate. Under the conditions described here it appears that about 5×10^4 μmoles of psilocin was liberated per unit of enzyme per hour. In contrast, dephosphorylation of disodium mono-phenylphosphate by alkaline phosphatase liberates about twice as much phenol and inorganic phosphate. In all instances liberation of inorganic phosphate follows closely the appearance of psilocin during incubation period.

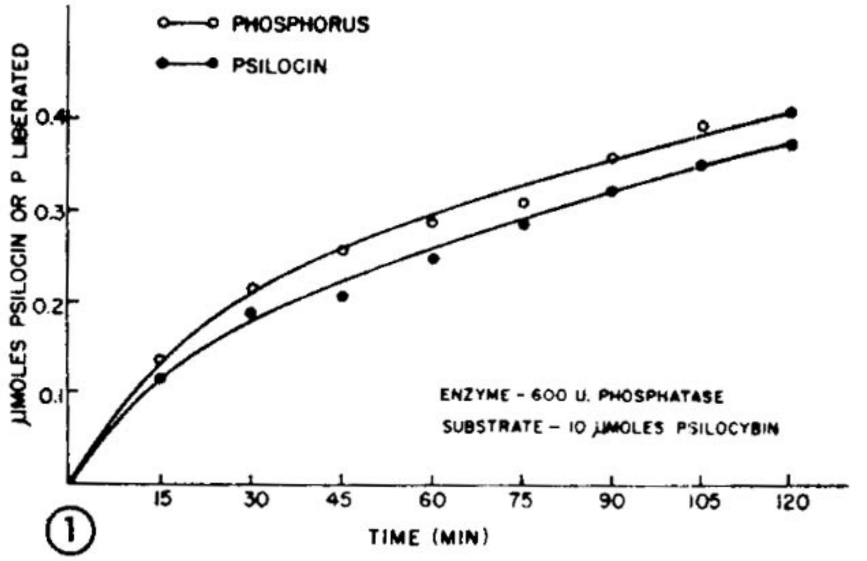


FIG. 1. Rate of phosphorus and psilocin liberation from action of purified alkaline phosphatase acting on psilocybin. Incubation in veronal buffer, pH 9.2 at 37°C.

That psilocin was liberated from psilocybin by phosphatase was evident not only from the colorimetric tests but also from the Rf values by paper chromatography. Development of the paper by spraying with the cinnamaldehyde-HCl reagent revealed only one spot identical in position with the standard psilocin strip. Average Rf value of both standard and unknown strips was 0.74 (average value of 4 strips). Psilocybin did not react with the reagent to give distinctive spot test.

The effect of psilocybin concentration on formation of psilocin is shown in Fig. 2. In these instances the incubation was carried out for one hour with 600 units of alkaline phosphatase. Concentrations of 1 μmole to 40 μmoles of psilocybin were employed as the substrate. A linear relationship between psilocybin concentrations and psilocin formation was noted up to about 4 μmoles of substrate. Beyond this concentration, rate of formation of psilocin approached a plateau, indicating saturation of the enzyme with excess substrate and attainment of a zero-order reaction.

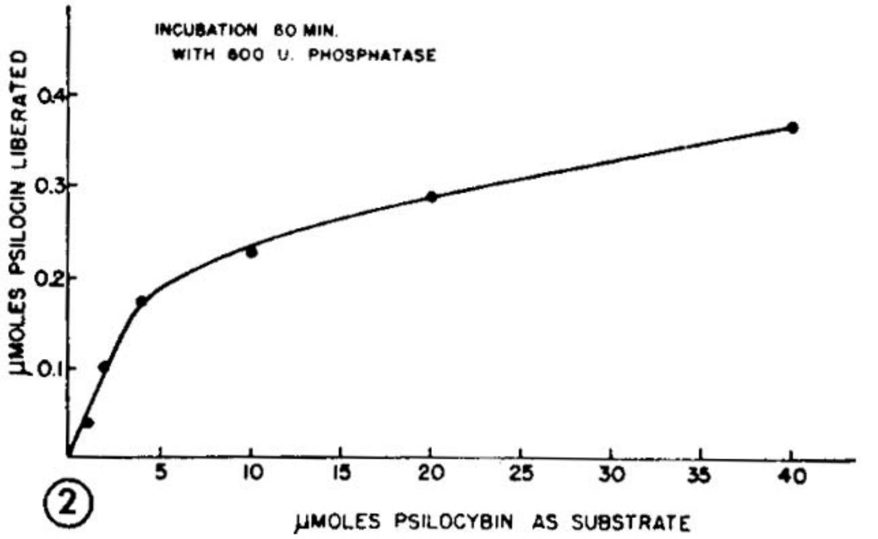

FIG. 2. Effect of psilocybin concentration on liberation of psilocin by purified alkaline phosphatase. Incubations were carried out in veronal buffer, pH 9.2 at 37°C for 60 min.

Since the Mg^{++} ion is known to activate alkaline phosphatase its effect was also studied with psilocybin as substrate. It was found that at concentrations of 0.35% $MgSO_4$, psilocin and inorganic phosphate liberated increased about 30% above controls.

Discussion

Psilocybin is readily dephosphorylated by intestinal phosphatase to form inorganic phosphate and psilocin. This raises the question of whether the central nervous system actions of psilocybin are produced by its dephosphorylated congener, since many mammalian tissues as well as serum contain a variety of phosphatases. Experiments in progress indicate that both mammalian tissue and plasma are capable of rapidly dephosphorylating psilocybin.

It would appear reasonable that psilocin might produce central nervous system effects of psilocybin since the latter would be highly ionized and less likely to penetrate the blood-brain barrier. Determinations of the solubilities of these 2 compounds in organic solvents and in Tyrode solution at pH 7.4 showed psilocin to be over 100 times as soluble in chloroform than was psilocybin (unpublished results).

Liberation of psilocin from psilocybin was readily determined by specific assay methods. Although closely related in structure, these 2 compounds reacted quite differently to various color reagents. We are currently exploring the possibility of utilizing the spectrophotofluorimeter as a means of identifying small amounts of both of these compounds.

Summary

Incubation of psilocybin with purified intestinal phosphatase resulted in liberation of psilocin and inorganic phosphate. Psilocin formed was determined both quantitatively by a specific colorimetric method employing the nitrosonaphthol reagent and qualitatively by paper chromatography. Some characteristics of the phosphatase action on psilocybin are described. The possibility of a similar reaction occurring in the intact animal is discussed.

Abstract

The following questions regarding the detection of psychoactive drugs in mushrooms are addressed: At what stage of the mushroom development can the psychoactive drugs psilocyn and psilocybin be identified, and what effect does light have on the growth of these mushrooms. To answer these questions, *Psilocybe cyanescens* Wakefield mushrooms were grown from their spores in a controlled setting. At various times of their development, samples were taken and analyzed for psilocyn and psilocybin. Knowing what stage of development the psychoactive drugs can be identified may be useful to law enforcement personnel and forensic chemists. Methanolic extracts of various samples were analyzed by TLC and by GC/MS. It was determined that the mycelium knot stage of the mushroom was the earliest stage at which the psychoactive drugs could be detected. It was observed that light affected the time of development and the appearance of these mushrooms.

Keywords: forensic science, psilocyn, psilocybin, psychotropic mushrooms

Law enforcement agencies in Minnesota are beginning to see an increased number of mushroom growing operations. Knowing what stage of development the psychoactive drugs can be identified may be useful to law enforcement personnel and forensic chemists. This information is important because in the state of Minnesota it is illegal to possess any material, compound, mixture or preparation which contain any quantity of psilocyn and/or psilocybin[1].

The word mushroom is a general term used to describe the relatively large and fleshy fruiting bodies of fungi, particularly all gill fungi. They are fungi that differ from plants in that these lack roots, stems, leaves, flowers, seeds and chlorophyll. Since mushrooms lack chlorophyll, they depend upon their surrounding medium for their nutrients. The vegetative portion of the fungus accumulates a reserve of food from the immediate surroundings in order to develop fruiting bodies[2-3].

Fungi are categorized as follows: kingdom, phylum, class, order, family, genus, and species. Mushrooms containing psychotropic drugs are classified in the kingdom Mycota, the phylum Basidiomycota, the class Hymenomycetes, and the order *Agaricales*. There are four families of mushrooms, *Strophariaceae*, *Bolbitiaceae*, *Coprinaceae*, and *Cortinariaceae*, that contain psilocybin, psilocyn, or related alkaloids with an indolic nucleus. The genus and species of *Psilocybe* mushrooms that were grown were identified as *Psilocybe cyanescens*. The pleurocystidia sizes noted in the keys describing the *Psilocybe cyanescens* mushroom varied slightly from the mushrooms grown. This may indicate a variant of this species (communication with Dr. David McLaughlin, Plant Biology Department, University of Minnesota)[2,4,5-8].

The four stages making up the life cycle of a mushroom are the spores, the mycelium, the primordia, and the mature fruit. The spores are the reproductive cells or "seeds" of the fungi (Fig. 1). Germination of the spores takes place when a suitable substrate and correct environmental conditions are present. These spores grow outward seeking nutrients and branch out forming a complex "coblike" system. This "cob-like" system is the vegetative portion of the fungus which is called the mycelium (Fig. 2). The mycelium absorbs water and nutrients from the substrate which is used in the production of the fruiting bodies. The ability of a fungus to begin fruiting is affected by genetic competence and various environmental factors including moisture, temperature, light, and aeration. The formation and growth of the fruiting bodies is known as primordia and has been referred to as "mycelium knots" and "pinheads." The "mycelium knot" is referring to the initial fruiting body that is formed when the mycelium clumps together and seems to form a "knot" (Fig. 3). This knot eventually grows into the "pinhead," a plump growth, yellow in color and with a brown tip (Fig. 4). The fruit is considered mature when it is able to disperse spores and begin this life cycle over again (Figs. 5-6)[2,9].

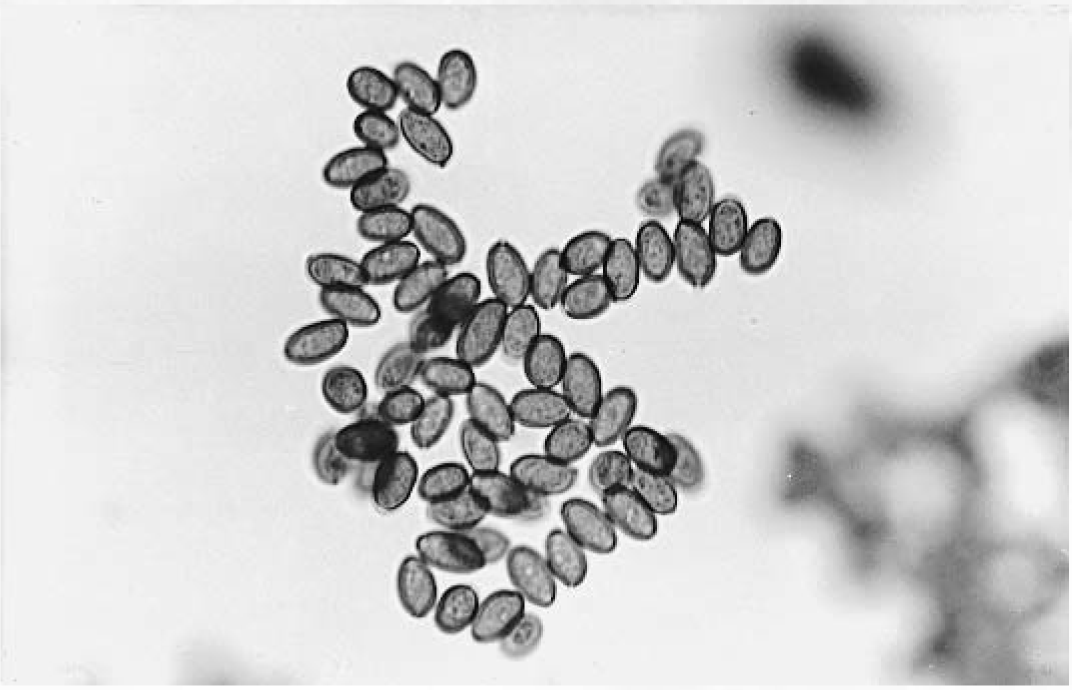

Fig. 1 - The aqueous spore solution viewed using a 1250 x magnification microscope. The spores are the first stage of the mushroom's life cycle. One milliliter of spore solution was used to inoculate each 1/2 pint jar.

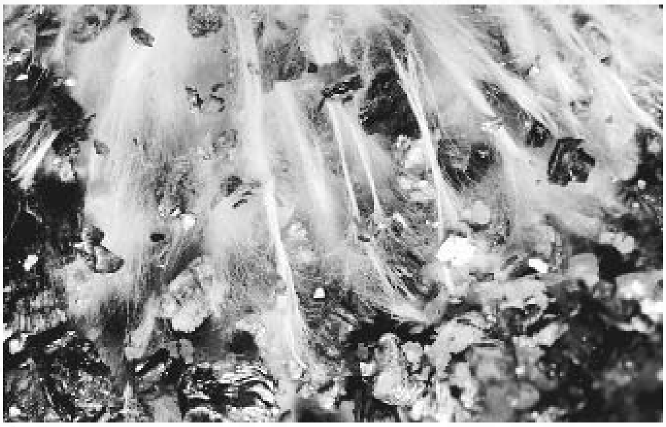

Fig. 2 - The vegetative portion of the fungus is called the mycelium. This is the second stage of the mushroom's life cycle. The first sign of mycelium growth appears 4 to 6 days after inoculation.

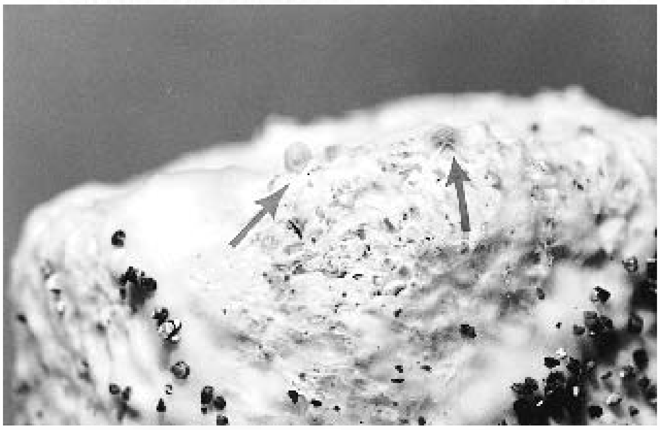

Fig. 3 - The third stage of the mushroom's life cycle is the primordia, and has been referred to as "mycelium knots" and "pinheads." The mycelium knots are the initial fruiting body that is formed when themycelium clumps together and seems to form a "knot".

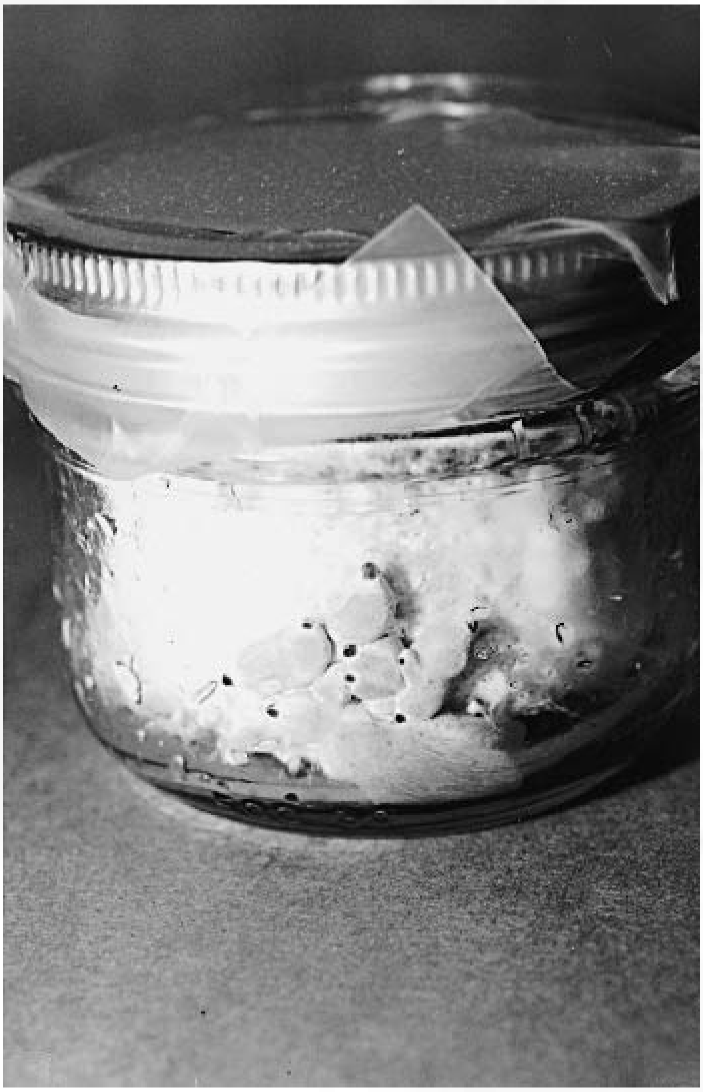

Fig. 4 - The third stage of the mushroom's life cycle is the primordia, and has been referred to as "mycelium knots" and "pinheads." The pinheads are plump growths, yellow in color with a brown tip.

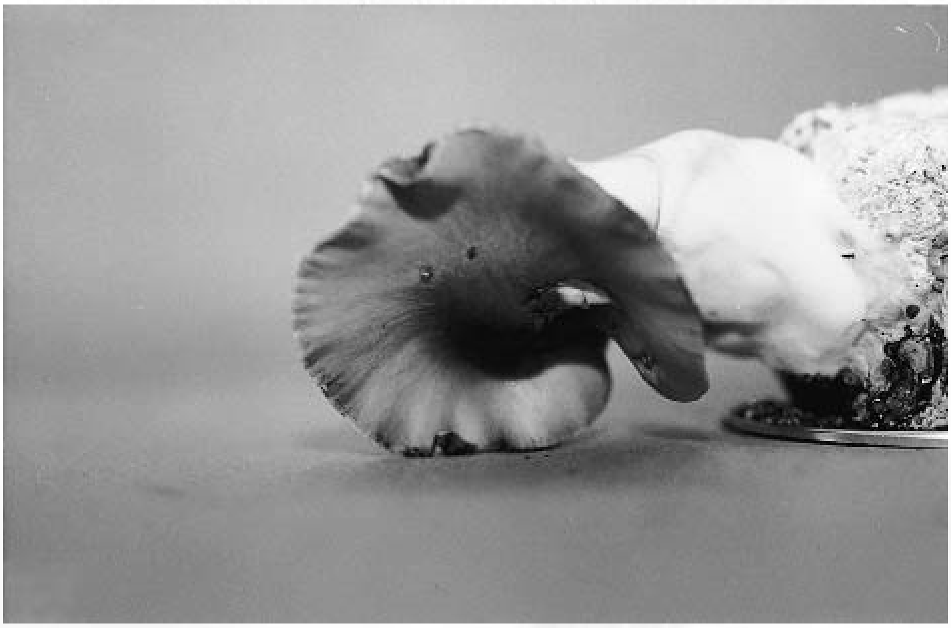

Fig. 5 - The fourth stage of the mushroom's life cycle is the mature fruit. Mushrooms are considered mature once they are able to disperse spores and begin the life cycle over again. Mature *Psilocybe cyanescens* Wakefield mushrooms.

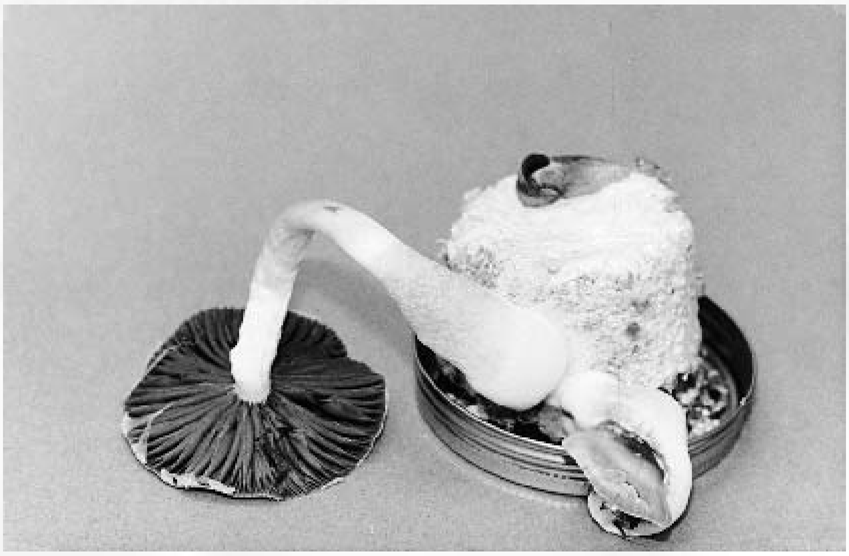

Fig. 6 - The fourth stage of the mushroom's life cycle is the mature fruit. Mushrooms are considered mature once they are able to disper se spores and begin the life cycle over again. Mature *Psilocybe cyanescens* Wakefield mushrooms.

Methods

The spores used in this experiment were obtained legally through an advertisement in *High Times Magazine* from Psylocybe Fanaticus (PFTek Seattle, WA). The spores were received in 10 mL syringes in an aqueous solution. The spore solutions were each viewed using a 1250x-magnification microscope.

Directions for preparing the growing media were received with the spores. Supplies used for the growing media were half-pint wide-mouth jars (Kerr Group, Inc. Jackson, TN), horticultural vermiculite (Schultz, St. Louis MO), brown rice powder and distilled water. The canning lids were prepared before the mixture was added to the jars. The rubber sealing edge of the canning lids were turned upwards and four holes were punched symmetrically around the outer edge. A mixture of 1/4 cup brown rice powder, 1/2 cup vermiculite and 1/4 cup distilled water was prepared for each 1/2 pint jar. This mixture was placed into the jars and covered with dry vermiculite. The lids were screwed on tightly and aluminum foil was used to cover the lids to prevent additional water from entering the jars during sterilization.

Since growing media is susceptible to contamination, the top layer of dry vermiculite was used to keep airborne contaminants from the wet substrate and absorb and regulate moisture transpiration and condensation[10]. The jars with the growing media mixture were sterilized at 120°C for 20 minutes. The jars were cooled before inoculation. Contamination was detectable through various colors from pastels to black. The growing media that became contaminated was observed but was not analyzed.

Eight jars per week were inoculated with 1 mL of spore solution. This was done for 9 weeks for a total of 72 inoculations. In addition to the eight jars inoculated per week, one jar per week was not inoculated and was used as a control blank. During the first four weeks, all samples were allowed to grow under indirect light. The last five weeks, half of the samples were allowed to grow under indirect light while the other half were kept in the dark. The jars kept in the dark were exposed to light only when samples were taken. Each jar was covered with parafilm after inoculation to keep airborne contaminates from the substrate.

The samples were transferred to terrariums after the pinheads became too large for the jars they were growing in. Two different terrariums were used for this experiment. The first one consisted of a styrofoam cooler with a piece of plexiglas inside of it. The second terrarium consisted of a 2-liter pop bottle with the middle portion cut out. To maintain a high level of humidity, both terrariums were sprayed with distilled water two to four times a day. Fanning the chamber with the lids two to four times a day also kept the terrariums well ventilated.

The growth and colonization was monitored for the samples grown under indirect light. The mycelium was sampled 13 days after inoculation. Samples were also taken from each jar at various stages of growth of the mycelium, primordia and the mature fruit. The growth of the mycelium, primordia and the mature fruit was monitored and compared for the samples grown under indirect light and in the dark simultaneously.

Sample Preparation

Samples were allowed to soak in methanol overnight. The methanol was decanted into a shell vial which was then condensed to near dryness (<1/2 mL) using a stream of air. An aliquot was removed for thin-layer chromatography (TLC). The mycelium knot samples were analyzed by TLC and by gas chromatography with a mass spectrometer (GC/MS) in this methanolic extract state without any clean-up.

The extracts were cleaned up with an acid solution for GC/MS analysis. A 0.2 N solution of sulfuric acid was used to resuspend and acidify the extract. This solution was washed twice with chloroform to remove the neutral organic compounds. The samples were made basic with sodium bicarbonate and the psychoactive drugs were extracted twice with chloroform. The chloroform was evaporated and the sample was reconstituted with methanol for GC/MS analysis.

Thin-Layer Chromatography

TLC was carried out on 5 x 10 cm silica gel plates (Analtech Newar, DE). Psilocyn (Alltech State College, PA) and psilocybin (Alltech State College, PA) standards were spotted on each plate along with the sample extracts. The plates were developed to 6 cm at room temperature in a covered development tank with a 9:1 chloroform/methanol solution. A beaker containing 3 mL of ammonium hydroxide was placed in the tank to assist in development. The plate was dried with low heat and visualized with a paradimethylaminobenzaldehyde (p-DMAB) spray reagent. (The p-DMAB reagent consisted of 2 g of p-DMAB in 50 mL of ethanol and 50 mL of hydrochloric acid.) The relative R_f value of psilocybin is 0.00 and the relative R_f value of psilocyn is 0.85.

The lower limit of detection was determined by serial dilutions of the psilocyn standard and spotting/developing it until the spot associated with the standard was not seen. The lower limit of detection for the TLC method was determined to be approximately 0.03 mg/mL.

Gas Chromatograph/Mass Spectrometer

The Hewlett Packard gas chromatograph 5890 Series II interfaced with the Hewlett Packard 5970 series mass selective detector (MSD) and the Hewlett Packard G1800A gas chromatograph detector system (GCD) were used for the detection of the analytes. These two instruments are equivalent and samples were run on specific instruments depending upon their availability. An HP-1 12 m column (film thickness 0.33 µm, column id 0.2 mm) was used for the gas chromatography (GC). The parameters for the GCD were as follows: injection port 250°C and detector temperature 280°C. *Method SCAN70* - Low mass 35, high mass 425, initial temperature 70°C, ramp rate 25°C/min and final temperature 300°C hold for 3.0 minutes. The parameters for the MSD were as follows: injection port 265°C and detector temperature 280°C. *Method SCN90* - Low mass 35, high mass 400, initial temperature 90°C, ramp rate 25°C/min, and final temperature 300°C hold for 4.0 minutes. Sample volume was approximately 3 µL with the split ratio of 30:1.

Lower Limit of Detection

The lower limit of detection for both instruments was determined by serial dilutions of the psilocyn standard and analyzing it until a peak at the correct retention time containing the prominent ions 44, 58, 77, 159, and 204 was not detected. The lower limit of detection was determined to be approximately 0.1 mg/mL for both instruments.

Results and Discussion

Identification of the mushrooms grown in this project was made by examination of the spores, fruiting bodies and the mature mushroom. Spores were examined for their color, shape, and size. The spores were purple to brown in color and elliptical to oblong elliptical in shape. They ranged is size from 6.7-8.2 µm by 12.6-15.0 µm. The fruiting bodies were examined mainly for color. The mature mushroom was examined for shape, size, color, texture, gill characteristics, and general appearance.

The original spore solutions were analyzed by TLC and by GC/MS. No psilocyn or psilocybin were detected in any of the spore solutions.

Mycelium growth was observed from 4 to 6 days. Fruiting bodies were observed from 24 to 48 days. The average amount of time for the primordia to appear was 32 days. Samples of mycelium were taken after 13 days of growth, 20 days of growth, and at various other days of growth. A total of 29 samples of the white mycelium growth were analyzed. No psilocyn or psilocybin was detected in any of these 29 samples. Nine of the 29 samples were confirmed by GC/MS, and again no psilocyn was detected.

Samples were analyzed after the first sign of growth of mycelium knots. A total of 22 mycelium knot samples were analyzed by TLC. Samples were considered to be consistent with a standard if their relative R_f value and their color matched the standard also spotted on the plate. Samples were considered to indicate a standard if their relative R_f value matched the standard but the color was not as dark as the standard spotted. Of the 22 mycelium knot samples, 17 were consistent with psilocyn. Of these 17 samples, 8 were also consistent with psilocybin and 1 indicated there was psilocybin in the sample. Four samples were consistent with the psilocybin standard spotted on the TLC plate, and one of these samples also indicated there was psilocyn in the sample. There was no psychoactive drugs detected in one of the samples.

Samples were analyzed after the first pinheads of the fruiting bodies were observed. A total of 25 samples of the pinheads were analyzed by TLC. All 25 samples were with the psilocyn standard spotted on the TLC plate. Of these 25 samples, 3 were also consistent with the psilocybin standard spotted and 3 indicated there was psilocybin in the sample (Table 1).

The 22 mycelium knot samples were also analyzed by GC/MS. In the inlet system of the gas chromatograph, thermal dephosphorylation of psilocybin occurs. As a result of this degradation of psilocybin to psilocyn, one is unable to differentiate the two by GC/MS. With this inability to differentiate psilocyn and psilocybin, it is unknown if the starting material contains psilocyn, psilocybin, or a mixture of both drugs. For this project, only a psilocyn standard was analyzed by GC/MS (Figs. 7-9). Samples were considered to be consistent with psilocyn if their retention time and mass spectral fragmentation pattern matched that of the psilocyn standard. Samples were considered to indicate psilocyn if their retention time was consistent with the psilocyn standard and contained the prominent ions, but were lacking ions in the total fragmentation pattern. Of these 22 mycelium knot samples, 12 were consistent with the psilocyn standard. Seven samples were found to indicate psilocyn, and there were three samples where psilocyn was not detected.

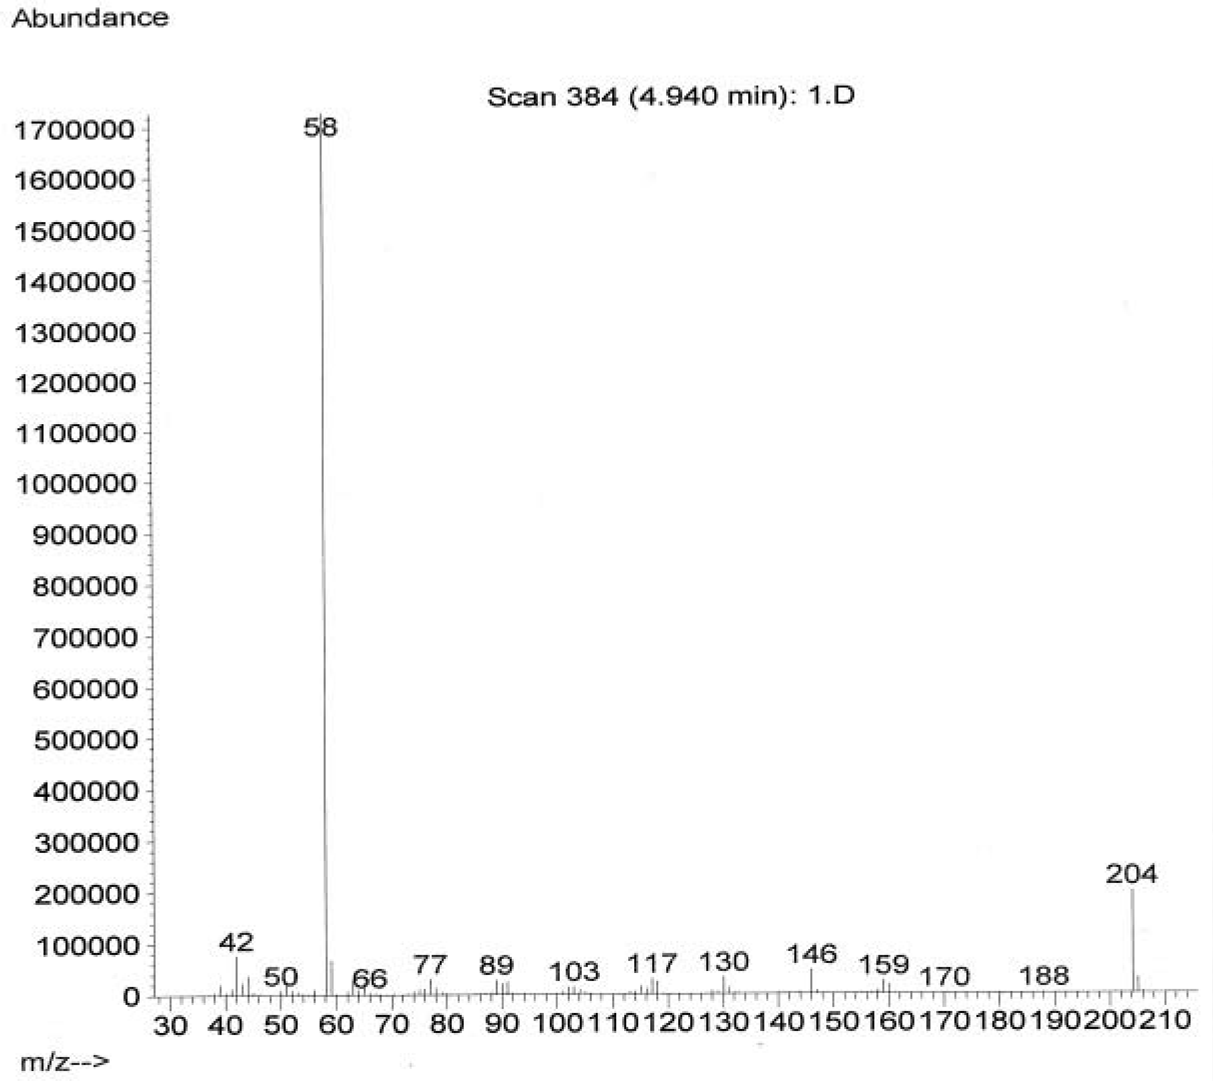

Fig. 11 - Mass spectrum of a mushroom sample analyzed on a Hewlett Packard 5970 series mass selective detector (MSD) with the following parameters: injection port 265°C and detector temperature 280°C. Initial temperature 90°C, ramp rate 25°C/min and final temperature 300°C with a hold of 4 min.

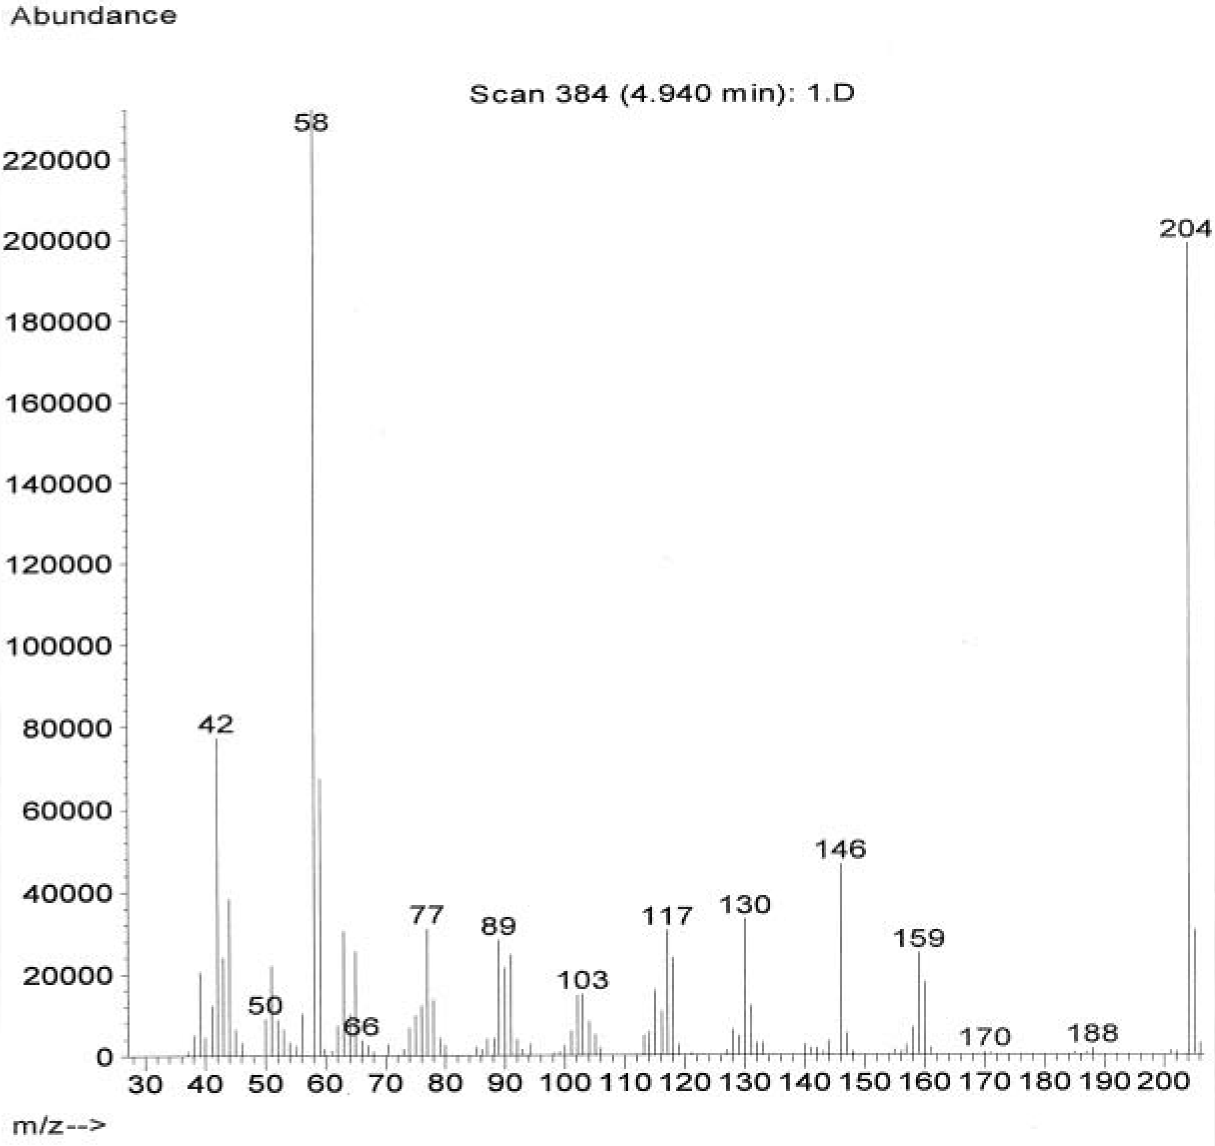

Fig. 12 - Expanded mass spectrum of a mushroom sample analyzed on a Hewlett Packard 5970 series mass selective detector (MSD) with the following parameters: injection port 265°C and detector temperature 280°C. Initial temperature 90°C, ramp rate 25°C/min and final temperature 300°C with a hold of 4 min.

There were some noticeable differences in the samples grown under indirect light versus the samples grown in the dark. All samples started to show mycelium growth at 4 days. The first signs of fruiting bodies were observed to be from 19 to 25 days in the samples that were grown under indirect light with the average being 21 days. The first signs of fruiting bodies were observed from 23 to 45 days for the samples that were grown in the dark, with the average being 26 days. The samples that were grown under indirect light had primordia which grew faster and larger. They were plump, yellow in color with brown tips. The samples that were grown in the dark had small white primordia that were skinny and long. The coloring was off-white with only a few having dark brown tips. The mushrooms that were grown under indirect light had thick stipes with yellowish to chestnut colored caps. The mushrooms that were grown in the dark had lighter stipes that were much skinner than the mushrooms grown in the light. The caps of the mushrooms grown in the dark were also lighter in color than the mushrooms grown under indirect light. Psilocyn and/or psilocybin was detected in the mycelium knots, the pinheads and the mature mushrooms of all samples grown either in the dark or the light.

Conclusion

The psychoactive drugs psilocyn and psilocybin were not detected in the mycelium, the earliest stage of development of the mushroom. These drugs were identified in the mycelium knots, the earliest stages of the fruiting body of the mushroom.

Light affects the growth of the *Psilocybe cyanescens* mushroom. This affect is apparent in the time of development and the appearance of the mushroom. Light affected the color and size of both the fruiting bodies and the mature mushroom. Light did not affect the presence of psilocyn or psilocybin in the early stages of the primordia or the mature mushrooms, nor did it affect the ability to detect these psychotropic drugs. It appears that the *Psilocybe cyanescens* mushrooms are not photosynthetic, but are photosensitive.

Acknowledgments

The author wishes to acknowledge Dr. David McLaughlin, Plant Biology Department, University of Minnesota for his time and assistance in identifying the mushroom, and his explanations about the classifications of fungi and the development of the mushroom. This project was supported by the Federal Bureau of Investigation, Minneapolis Office which generously provided the supplies.

Abstract

The use of mushrooms containing the hallucinogenic substance psilocybin for intentional intoxication is relatively common. Occasionally, this results in adverse reactions with typical tachycardia that is not evidently caused by psilocybin. This study demonstrates the presence of phenylethylamine in the species Psilocybe semilanceata using gas chromatography-mass spectrometry and shows that the amount of this substance may vary much more than that of psilocybin. The highest amount of phenylethylamine (146 µg/g wet weight) was observed in mushrooms from a case of three young men hospitalized because of adverse reactions. Comparison of the symptoms observed in clinical cases of magic mushroom intoxication with those after intake of pure psilocybin or phenylethylamine suggests that phenylethylamine might have a role in the development of adverse reactions to *Psilocybe* mushroom intake.

Introduction

Magic mushrooms, which contain the hallucinogenic indole derivative psilocybin (Figure 1), are naturally occurring throughout the world. Abuse of hallucinogenic mushrooms is relatively common, and among young adults, it is one of the most frequently reported illicit drugs after cannabis[1-5]. Apart from inducing drug-seeking behavior, such abuse entails a risk of adverse effects that require hospitalization. Pronounced adverse reactions after ingestion of psilocybin-containing mushrooms are reported to occur with a frequency of 13%[6]. However, the exact mechanism of action and pharmacologic profile of pure drug compared with mushroom preparations remain to be fully elucidated[6,7].

Prison inmates discovered to be using magic mushrooms for intentional intoxication tested positive in the urine drug screening for the amphetamine class of compounds when a polyclonal antibody assay kit with a broad substrate reactivity was used. Because the assay does not detect psilocybin or its active metabolite, psilocin, the presence of an unknown compound structurally related to amphetamine was indicated. We therefore undertook this investigation of *Psilocybe semilanceata* (Liberty cap), which is the most common indigenous psilocybin-containing mushroom species.

Experimental

Chemicals

Phenylethylamine (PEA) hydrochloride was obtained from Sigma Chemical (St. Louis, MO) and psilocybin from Sandoz (Basel, Switzerland).

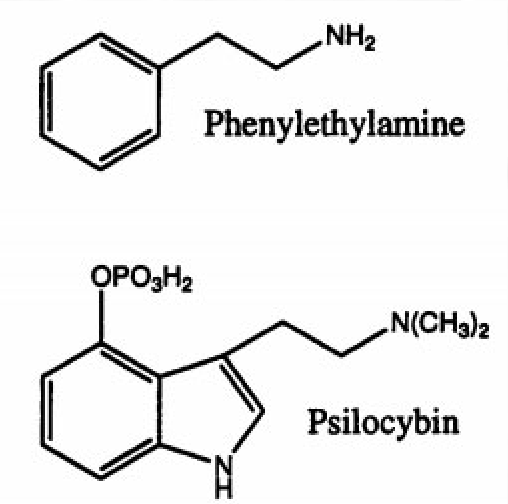

Figure 1. Chemical structures of phenylethylamine (PEA) and psilocybin.

Specimens

Wild mushrooms were obtained fresh directly from different locations in Sweden and in connection with a case of three young men (ages 21-25 years) being hospitalized because of adverse reactions after eating magic mushrooms. The identity of the studied mushrooms as *Psilocybe semilanceata* was confirmed by macroscopic and microscopic inspection. Specimens were either stored refrigerated for up to one week and then transferred to plastic containers and stored in methanol at -20°C or air dried and stored in a closed container at ambient temperature. The specimens were prepared for analysis by disintegration of tissue in methanol (1-5 g mushroom/25 mL methanol) using an Ultra-Turrax T25 (Janke & Kunkel, Staufen, Germany). Repeated freezing and thawing or sonication of tissue did not increase the recovery of substances (results not presented).

Chemical analysis

High-performance liquid chromatographic assay of psilocybin was performed on diluted (1000-fold with water) mushroom extracts using reversed-phase chromatography (150 x 4.0 mm Nucleosil C_{18}, 3 µm) with fluorescence detection (Shimadzu 551, Shimadzu Corp., Kyoto, Japan) and excitation and emission wavelengths at 270 and 330 nm, respectively. The mobile phase was composed of 10 mmol/L sodium phosphate, pH 3, with 6% (v/v) acetonitrile and 1% (v/v) methanol, and the flow rate was 1.0 mL/min. Aliquots of 20 µL were injected, and the detector response was linear in the concentration range used (0-1.4 mg/L). The intra-assay coefficient of variation (CV) was < 2% at a concentration of 0.24 mg/L.

Gas chromatographic (GC) analysis of PEA was performed using an HP 5890 GC (Hewlett-Packard, Palo Alto, CA) with a nitrogen-phosphorus detector (NPD) and a 25-m Chrompack WCOT CP-Sil 8CB fused-silica column (Chrompack Int. BV, Middelburg, The Netherlands) with a 0.25-ram internal diameter and 0.25-µm film thickness. Aliquots (10-500 µL) of the methanolic mushroom extracts were diluted with 3 mL phosphate buffer, and after addition of 0.6 mL 1 mol/L NaOH, they were extracted with 5 mL of 3% isopropanol in chloroform. The organic phase was extracted with 1 mL 0.1 mol/L H_2SO_4 and the aqueous phase transferred to new tubes. The extracts were alkalinized by addition of 0.2 mL 1.5 mol/L NaOH and extracted with 0.15 mL chloroform. Aliquots (1-2 µL) of the organic layer were injected into the GC system. The intra-assay CV was 5.0% at the level of 550 µg/L.

Gas chromatographic-mass spectrometric (GC-MS) analysis of PEA was performed using an ITS 40 WITNESS system (Finnigan MAT, San Jose, CA). Aliquots (10-100 µL) of the mushroom methanol extracts were diluted with 3 mL 0.1 mol/L sodium phosphate buffer, pH 6.0, and applied onto Certify Bond-Elut (Analytichem, Harbor City, CA) solid-phase extraction cartridges (prepared with methanol and 0.1 mol/L sodium phosphate buffer, pH 6.0). The columns were washed with 1 mL 1.0 mol/L acetic acid and 6 mL methanol and finally eluted with 2 mL ethyl acetate containing 2% ammonia. The volume of the eluates were reduced to approximately 100 µL by evaporation, and the residue was treated with 70 µL heptafluorobutyric anhydride (Supelco, Bellefonte, PA) at 75°C for 60 min. After cooling, 0.5 mL ethyl acetate was added, and 1-µL aliquots were injected into the GC-MS system.

Clinical cases

Clinical data were collected from hospital case records sent to the Swedish Poisons Information Centre concerning *Psilocybe* mushroom poisoning during the period over 1980-1995. The total number of patients was 25, of which 21 were between 19 and 27 years of age. Five of the cases occurred in 1995.

Results

Chemical investigation

Psilocybin was detected in all mushrooms identified as *Psilocybe semilanceata*. The identification of PEA (Figure 1) in mushroom extracts was based on coelution with authentic compound in the GC system with components in underivatized form, and in the GC-MS system (Figure 2) with components in derivatized form. PEA was the major component seen in the chromatograms from both the GC and GC-MS analyses. In addition, mass spectral identification of PEA was performed after derivatization with heptafluorobutyric anhydride (Figure 3). The agreement of GC and GC-MS data with authentic compound confirmed the identity of PEA in the mushroom specimens.

PEA was readily detectable in all mushroom specimens. The amount of PEA was always less than that of psilocybin, but a much greater variability in PEA content was demonstrated (Figure 4). However, there was good agreement between samples collected in the same location and at the same time (see samples 2a-c in Figure 4). Sample 4 in Figure 4 contained the highest amount of PEA (146 µg/g wet weight) and came from a clinical case of hospitalization after the ingestion of magic mushrooms.

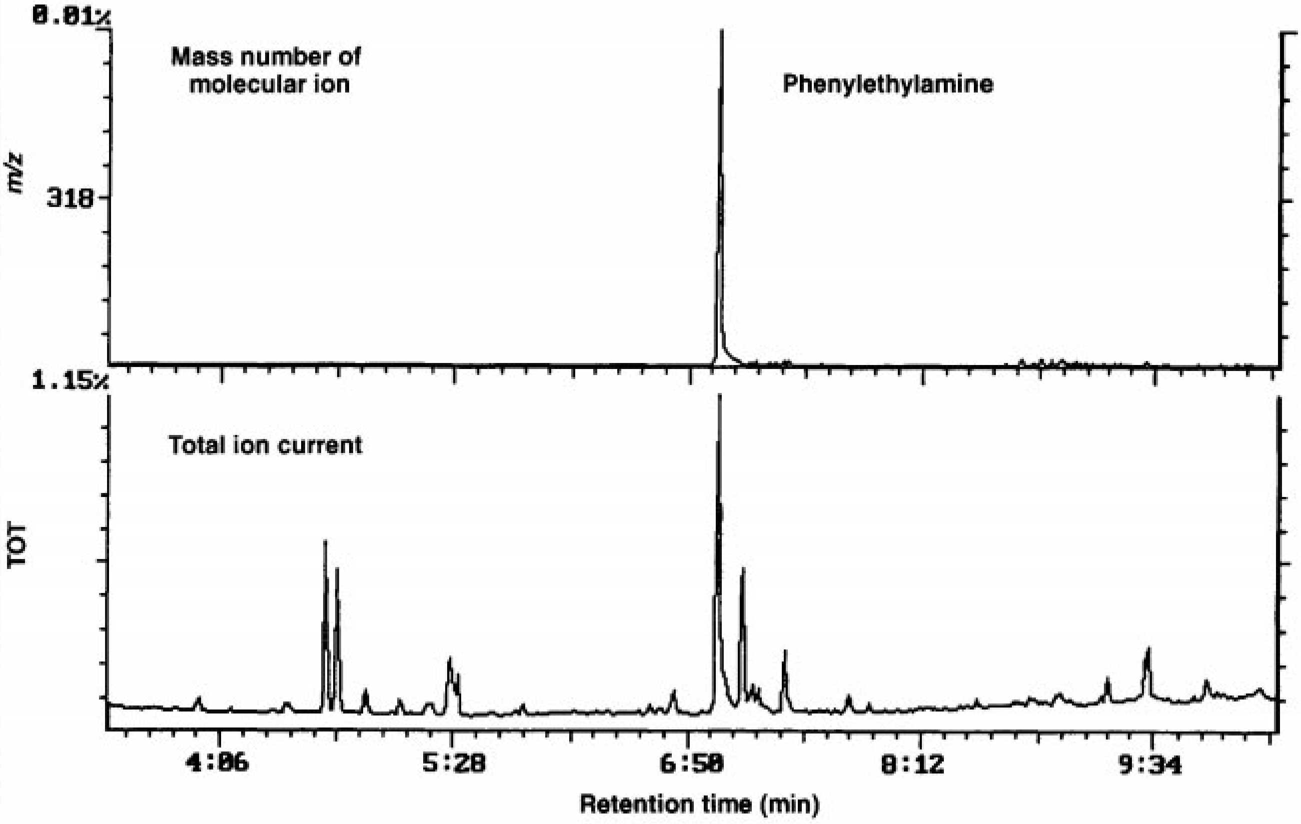

Figure 2. Total ion (lower trace) and selected ion (upper trace) chromatograms from the GC-MS analysis of a *Psilocybe* mushroom extract. The peak occurring at the retention time of phenylethylamine (PEA) is predominating. A peak at the same retention time is also seen in the trace for *m/z* 318 which corresponds to the molecular ion of PEA.

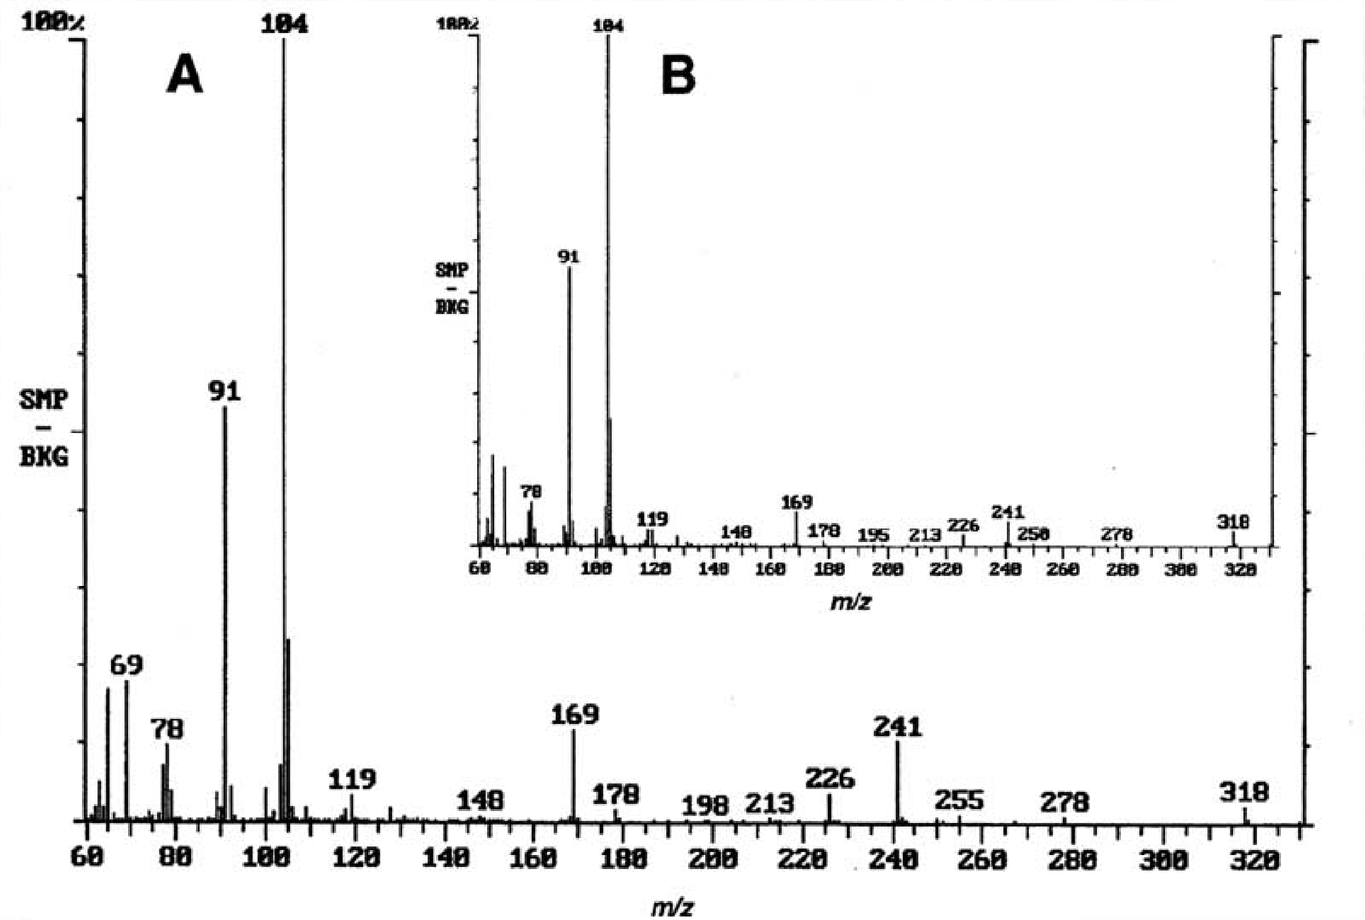

Figure 3. Electron impact mass spectra of unknown in mushroom extract (B) and reference phenylethylamine (A) as heptafluorobutyryl derivative.

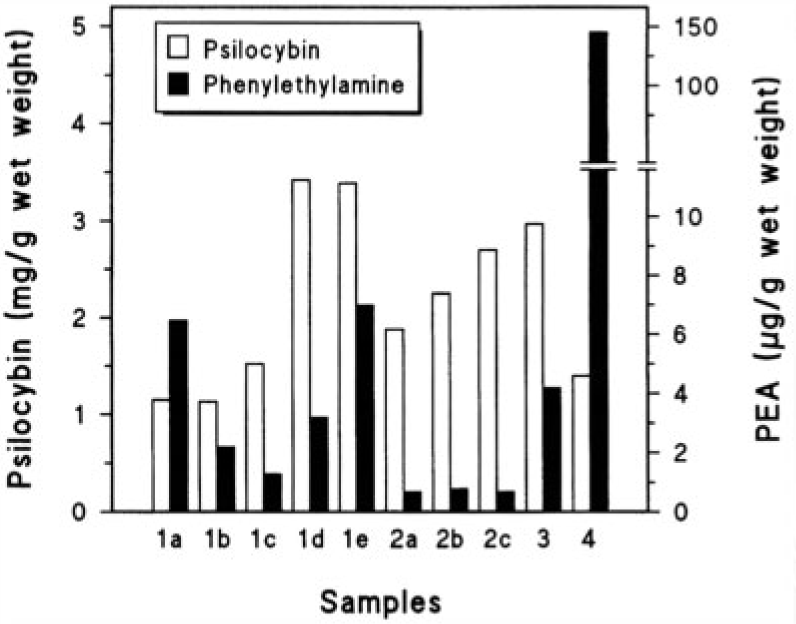

Figure 4. Psilocybin and phenylethylamine (PEA) levels in *Psilocybe semilanceata* mushrooms collected at four different locations (1-4) in Sweden. Multiple collections from a single location are indicated by alphabetic notation (a-e). Sample 4 was obtained from a case of mushroom intoxication that led to adverse reactions and hospitalization.

Clinical symptoms of intoxication

Recorded symptoms in hospitalized patients with adverse reactions to *Psilocybe* mushroom ingestion reported to the Swedish Poisons Information Centre are listed in Table 1. The results are presented together with data compiled from the literature regarding clinical effects of mushroom ingestion as well as of pure psilocybin and PEA substances.

Discussion

The present study provides original evidence for the presence of the pharmacologically active substance PEA in *Psilocybe semilanceata*. PEA, the decarboxylated product of the ubiquitous amino acid phenylalanine, has received considerable interest within psychiatric research[8]. Increased formation and excretion of PEA has been associated with psychosis in patients and implicated in the etiology of mental disease[9,10]. Food is an exogenous source of PEA, which is present in chocolate, cheese, and wine, and has been implicated in the precipitation of dietary migraine[11]. However, to our knowledge, PEA has not been previously identified in any species of mushroom.

The pharmacological mode of action of PEA is not fully elucidated, but it has been reported to exert amphetamine-like activity and to have peripheral sympathomimetic effects[6,7,12,13]. The neurophysiological effects have been related to the enhancement of catecholaminergic activity[8]. Systemic administration of PEA produces behavioral effects in rats and mice[14]. The serotonergic system is thought to mediate the neurophysiological responses to hallucinogens[15,16]. It is therefore interesting to note that serotonin receptor blockade can potentiate the behavioral effects of PEA[17]. Although PEA resembles amphetamine structurally, it is seemingly not a substance with potential for abuse. However, despite substantial literature on the physiological functions of PEA, available data on its pharmacological effects in humans are more limited. In three reported cases in which PEA was unintentionally taken instead of amphetamine, the adverse reactions resulted in hospitalization[18]. The symptoms observed in these specific cases are listed in Table 1 with our own and previously published clinical data from Psilocybe mushroom intoxications[19,20] and a controlled experiment using pure psilocybin substance[21]. There are appreciable differences between the symptoms observed after psilocybin ingestion and mushroom intoxication. Visual hallucinations and euphoria occur less frequently after mushroom ingestion, which might be explained by a bias in selection of only those patients admitted to the hospital. However, tachycardia was observed in only 1 of 14 volunteer subjects given pure psilocybin, and this small influence on the heart rate has been observed by others[22,23]. In contrast, tachycardia is a common finding in patients intoxicated by *Psilocybe* mushrooms, an observation that also points toward a role for PEA in the adverse effects of such mushroom ingestion.

Within the human body, PEA is formed at a high rate, but it is also rapidly inactivated through metabolic breakdown by monoamine oxidase (MAO), which leads to the formation of phenylacetic acid[8]. PEA is metabolized mainly by the MAO-B isozyme, which is found in serotonergic regions of the human brain[24]. Ingested psilocybin readily becomes dephosphorylated to psilocin, which is further inactivated by MAO, leading to formation of 4- hydroxyindoleacetic acid[25]. However, this has been shown in the rat to be a minor metabolic pathway, which indicates that psilocin is a poor substrate for MAO. Whether psilocin is a MAO-A or B substrate has not been clarified, but the effect of its structural analogue *N,N*-dimethyltryptamine (DMT) is greatly enhanced by the coingestion of MAO inhibiting substances[26]. Thus, although speculative, a metabolic interaction between PEA and psilocin through competitive inhibition of MAO is possible.

The presence of PEA in a common species of hallucinogenic mushrooms may have implications for drugs-of-abuse testing because we have occasionally detected PEA in urines testing positive for the amphetamine class of compounds by immunoassay technique (unpublished observation). As a consequence, ingestion of magic mushrooms should be considered in such cases. Today, *Psilocybe* mushroom abuse is generally not screened for in drugs-of-abuse testing despite the reports of common usage[1-5]. Using reagent kits sensitive to PEA and including psilocin in the verification assay might offer a means of detecting this kind of drug abuse.

In conclusion, we have shown that PEA is readily present in the hallucinogenic mushroom species *Psilocybe semilanceata*. The high amount of PEA observed in mushrooms obtained from one case of intoxication suggests that PEA may contribute to the adverse reactions. The much higher variability in PEA content as compared with psilocybin is intriguing because it could explain why adverse reactions occur only in certain cases. Future studies will need to determine the factors influencing PEA formation in *Psilocybe semilanceata* and determine if PEA is present in other common hallucinogenic mushroom species being used for intoxication.

Acknowledgments

We kindly thank Dr. Åke Strid (Sektionen för Kryptogarnbotanik, Naturhistoriska Riksmuseét, Stockholm) for mushroom collection and for expert assistance with the identification and Lennart Wessberg (Sollefteå) and Svengunnar Ryman (The Herbarium, Uppsala University, Uppsala) for providing us with mushroom samples. Elisabeth Gräinsström is acknowledged for initiating this study by the observation of mushroom use by prison inmates.

A sequence of "peculiar" cases

Mushroom intoxications have been noted throughout history. One 11th Century episode in Japan allegedly involved some Buddhist nuns who became lost in the forest. After eating some wild mushrooms, they felt compelled to dance. Some woodcutters who were also lost happened along, indulged in the peculiar fungus and joined the nuns in dancing. This tale has been handed down in the *Konjaku Monogatori* ("Tales of Long Ago") and the legendary toadstools became known first as dancing mushrooms (*maitake*) and later as laughing mushrooms (*waraitake*) (Sanford 1972; Wasson 1973). While the identity of the causative fungus is unknown, *Panaeolus papilionaceus* (Fries) Quélet has been suggested as one possible candidate (Sanford 1972; Wasson 1973). Sanford (1972) notes that Seichii in his *Genshoku Nibon kinrui zukan* (Icones of Japanese Fungi) quotes a 1917 episode from a newspaper article:

> Mr. Taniguchi (age 31), Mrs. Taniguchi [age 35], and Mrs. Taniguchi's brother, Buntsuke (age 41), treated themselves to two bowls of mushroom soup while the elder Mrs. Taniguchi (age 71) ate one bowl with only two or three mushrooms in it. They had hardly eaten when first Mrs. Taniguchi and then Mr. Taniguchi began to feel odd. Mr. Taniguchi then went next door to ask someone to fetch a doctor. When he got back home he found his wife dancing around stark naked, playing an imaginary *shamisen*, and laughing raucously. Even as he stood there amazed at all the uproar he found that he too was falling into the same crazed state. The older brother also eventually began to dance crazily. The intoxication of Taniguchi's mother was weaker, however, and though she became muddled she never lost complete control of her senses. She did, however, keep repeating the same words over and over and went to every house in the neighborhood apologizing throughout the night for "preparing such a poor meal" and thanking everyone "for putting up with it."

Dr. Seichii was "able to obtain samples of the mushrooms involved and solidly identify them as none other than *Panaeolus papilionaceus*" (Sanford 1972).

In 1816 a poor man gathered what he believed to be common ordinary meadow mushrooms in Hyde Park, London. Soon after commencement of his stewed mushroom meal, "he was, to use his own expressions suddenly seized with a dimness or mist before his eyes, lightness and giddiness of his head, with general trembling and sudden loss of power, - so much so, that he nearly fell off the chair; to this succeeded, loss of recollection; he forgot where he was, and all the circumstances of his case." Later it was observed that the patient "suffered much from giddiness, and was greatly inclined to sleep; his pulse was slow and feeble." The mushrooms were identified as *Agaricus campanulatus* Linnaeus, the cause of a similar case that had been reported in the September 1815 issue of *Gentleman*'s *Magazine* (Glen 1816). *A. campanulatus* later become known as *Panaeolus campanulatus* (Fries ex Linnaeus) Quélet and its reputation of possessing sedative properties persisted into the 20th Century (McIlvaine 1973). Thus Krieger (1911) suspected this species to have caused an intoxication following ingestion of what the victim presumed were shaggy manes (*Coprinus comatus*). *Panaeolus papilionaceus*, in contrast, had gained quite a different reputation in North America (McIlvaine 1973):

> I have seen it produce hilarity in a few instances, and other mild symptoms of intoxication, which were soon over, and with little reaction. But I have seen, at table, the same effects from eating preserved peaches and preserved plums which had fermented. Many personal testings have been without effect. Testings upon others vary with the individuals. The fungus seems to contain a mild stimulant. It is not dangerous, but should be eaten with caution. Being of small size, and not a prolific species, quantities of it are difficult to obtain. Moderate quantities of it have no effect whatever.

In 1914, a classic case of psilocybian mycetismus occurred in Maine after Mr. W., a middle-aged avid mycophile, "strictly temperate in his habits," and his adult niece consumed mushrooms (perhaps a pound fresh weight) fried in butter and which he had identified as the butterfly *Panaeolus*, i.e., *P. papilionaceus* (Verrill 1914).

> Next, say about half an hour after eating, both of us had an irresistible impulse to run and jump,

> which we did freely. Soon both of us became very hilarious, with an irresistible impulse to laugh and joke immoderately, and almost hysterically at times. The laughing could be controlled only with great difficulty; at the same time we were indulging extravagantly in joking and what seemed to us funny or witty remarks. Mr. Y., who was with us, said that some of the jokes were successful; others not so, but I can not remember what they were about.

Later during the experience Mr. W.

> had a very disagreeable illusion. Innumberable human faces, of all sorts and sizes, but all hideous, seemed to fill the room and to extend off in multitudes to interminable distances, while many were close to me on all sides. They were grimacing rapidly and horrible and undergoing contortions, all the time growing more and more hideous. Some were upside down.

Eidetic imagery was very prominent as the

> faces appeared in all sorts of bright and even intense colors - so intense that I could only liken them to flames of fire, in red, purple, green and yellow colors, like fireworks.

Macropsia was also evident as Mr. W. felt his body "elongate upward to the ceiling ... like Jack's bean-stalk..." Soon he experienced his body collapse to its natural height. "The entire experience lasted six hours. No ill effects followed" (Verrill 1914).

In 1916, a *Panaeolus* species appeared in a New York mushroom house and surprisingly was consumed unnoticed amongst commercial *Agaricus*. Murrill (1916), believing this "dangerous" mushroom to be a new species, designated it *P. venenosus* Murrill. Shortly thereafter, Douglass (1917), a surgeon, described the experience resulting after his maid, wife, and he himself had eaten some *Panaeolus* (later determined by Murrill to be *P. semiglobatus* Murrill *nomen nudum*) gathered in a cucumber bed in Maine. Despite the fact that Douglass attempted management with intravenous morphine and atropine, he later concluded that the "pilzatropin" contained in *Panaeolus campanulatus*, *retirugis*, *semiglobatus*, and *venenosus* produced symptoms that were "purely those of a stimulated nervous system" and could not "conceive that a full meal of these mushrooms could cause death" (Douglass 1917). Without citing any specific cases and apparently unaware of the mushroom poisoning classification proposed by Douglass, Ford (1973) coined the categorical term "Mycetismus Cerebralis" for this "peculiar poisoning" and mentioned *P. campanulatus* and *P. papilionaceus* as being responsible.

Reports of accidental *Panaeolus* poisonings have not been limited to Europe and the U.S. In the early 1940's a rash of such intoxications occurred in Australia. *Panaeolus ovatus* Cooke & Massee became known as the "hysteria fungus" since patients were sometimes admitted to the hospital after beginning "to feel numbness in arms and legs, to see coloured lights and to become almost hysterical" (Trotter 1944). One patient was quoted as having felt as if he "had been on a bender." Treatment generally consisted of administration of an emetic such as zinc sulfate and hospitalization was for never more than overnight.

In 1957, between a half and one hour after enjoying some little dung-inhabiting mushrooms, a victim of mushroom poisoning in Bremen, Germany began to notice "glimmers" before his eyes. Three attempts at vomiting were unsuccessful and he felt weak with occasional shortness of breath. He was hospitalized and given charcoal in four glasses of water and an injection of apomorphine to induce vomiting. He received gastric lavage and intravenous fluids. After a two day stay, all was in order. The fungus responsible was identified afterwards as *P. papilionaceus* (Bull. ex Fr.) Quélet (von Neuhoff 1958).

In August, 1965, an important case was documented from the French Mediterranean (Heim; Hoffmann & Tscherter, 1966). It involved a woman and her two children (ages 11 and 14). After unsuspectingly eating a meal of *Panaeolus cyanescens* (Berkeley & Broome) Saccardo, the mother experienced terrifying hallucinations and was treated with gastric lavage and sedatives. While the elder child experienced visual echo patterns and was incapable of raising himself from an armchair, the younger convulsed and lost consciousness, thus exhibiting "an extreme neurophysiologic manifestation of the cerebral excitation syndrome" (Pollock 1974).

Panaeolian chemo-taxonomy

On the basis of some of the preceding scattered reports implicating *Panaeolus* species as the provokers of cerebral mycetisms, the suggestion by Schultes (1939; 1940) that *Panaeolus campanulatus* Linnaeus var. *sphinctrinus* (Fr.) Bresadola (now considered to be a separate species, *sphinctrinus*) was the *teonanácatl* of the Aztecs seemed quite convincing. Ethnobotanical studies by the Wassons, Heim, and other collaborators, however, suggested that *Psilocybe* species, *Stropharia cubensis* Earle, and possibly even *Conocybe siligineoides* Heim, rather than *Panaeolus* were employed for magico-religious purposes (Heim, Wasson & Collaborators 1958). Guzmán (1959) even referred to *P. sphinctrinus* as the "false" *teonanácatl*. Nevertheless, the isolation of crystalline psilocybin from *P. sphinctrinus* mushrooms (RP1 strain) grown on compost certainly established the hallucinogenic potential of that species (Heim, Wasson & Collaborators 1958). Soon afterwards, Hofmann, Heim & Tscherter (1963) were not able to substantiate their findings by analysis of other samples of *P. sphinctrinus*. Unfortunately, neither the specimen sources nor herbarium reference numbers were cited in either study. Although serotonin (5-hydroxytryptamine) was found to be present in carpophores of *Panaeolus campanulatus* (Fr.) Quélet - from Washington and Idaho, *P. foenisecii* (Fr.) Kühner - from Washington and Michigan, *P. acuminatus* (Schaeff. ex Fr.) Quélet - from Washington, *P. fontinalis* Smith - from Michigan, *P. semiovatus* (Fr.) Lundell - from Michigan, *P. subbalteatus* (Berkeley & Broome) Saccardo - from Michigan, and *P. texensis* Tyler & Smith - from Texas; no 4-hydroxytryptamine derivatives such as psilocin were detected in these species (Wier & Tyler 1963; Tyler & Smith 1963). Later studies with Argentinian specimens of *P. sphinctrinus* also revealed the presence of serotonin but no 4-hydroxytryptamine derivatives (Tyler & Gröger 1964). One point was clear - *Panaeolus sphinctrinus* was certainly a "mystifier."

Ola'h (1970) thus undertook a systematic study of the genus *Panaeolus*, chemically analyzing various samples which consisted of: a) wild carpophores, mycelia and carpophores obtained in culture; b) wild carpophores and mycelia; c) mycelia and carpophores obtained in culture; or d) mycelia only. This investigator assayed twenty-three samples of *P. sphinctrinus* twenty of which were from Quebec and one of which was the RP1 strain, revived from spore after seven years. Thirteen samples, including mycelia of the RP1 strain, were found to contain psilocin and seven of these also contained psilocybin. Five samples of *P. foenisecii* (four from Quebec and one from Paris) were studied chemically. Two from Quebec contained both psilocin and psilocybin, whereas the one from Paris and one of the two other Quebec samples contained psilocin. Of ten samples of *P. fimicola* (Fr.) Quélet, five were found to contain both psilocin and psilocybin. A sample of *P. microsporus* Ola'h & Cailleux was shown to produce psilocin but not psilocybin in carpophores derived from culture and neither compound was detected in the mycelia. This characteristic was transmitted into two successive generations also studied. A sample of *P. castaneifolius* (Murr.) Smith from Quebec contained psilocin in the wild carpophores, mycelia and carpophores obtained in culture, but psilocybin occurred only in the mycelia. This same pattern was found also in the next generation of this sample. Four samples of *P. africanus* Ola'h were capable of synthesizing psilocin and psilocybin in the mycelial stage and one of these was shown to produce psilocin in carpophores from culture. Because of these irregularities in psilocin and psilocybin biosynthesis, *P. africanus*, *castaneifolius*, *fimicola*, *foenisecii*, *microsporus*, and *sphinctrinus* were classified as "latent psilocybian" species (Ola'h 1969; Ola'h 1970).

A sample of *P. ater* (Lange) Kühner & Romagnesi from the East Indies was found to contain psilocin and psilocybin in mycelia and carpophores obtained in culture. Wild carpophores were not chemically examined and these findings were consistent in the next generation. Four samples of *P. cambodginiensis* Ola'h & Heim, consisting of mycelia and fruiting bodies from culture, contained both psilocin and psilocybin. Both of these indoles were also detected in wild carpophores, mycelia and carpophores from culture of *Panaeolus cyanescens* (Berkeley & Broome) Saccardo from Menton, France and an additional source. The same pattern was observed also in the next generation of the Mediterranean source. A sample of *P. subbalteatus* (Berkeley & Broome) Saccardo from Quebec was determined to possess both psilocin and psilocybin in wild carpophores and mycelia from culture. Likewise, *subbalteatus* from Paris synthesized psilocin and psilocybin in the mycelia, and psilocin was found in wild carpophores of that sample (data on psilocybin not presented for those carpophores). Neither psilocin nor psilocybin could be detected in mycelial cultures of *subbalteatus* from two other sources, one of which is the American Type Culture Collection. Three samples of *P. tropicalis* Ola'h were found to contain psilocin and psilocybin in wild and cultivated carpophores and mycelia. As a result of these findings, Ola'h (1969; 1970) placed *P. ater*, *cambodginiensis*, *cyanescens*, *subbalteatus* and *tropicalis* in the category of frankly "psilocybian."

Three samples of *P. acuminatus* (Schaeff. ex Fr.) Quéllet were negative for psilocin and psilocybin. Seven samples of *P. campanulatus* (Fr. ex L.) Quélet were also found to be negative for psilocin and psilocybin. One sample of *P. leucophanes* (Berkeley & Broome) Saccardo and its next generation were also lacking psilocin and psilocybin. Mycelia and cultivated carpophores of two samples of *P. retirugis* (Fr.) Quélet and their next generations were negative for psilocin and psilocybin as was one sample of *P. semiovatus* (Fr.) Lundell & Nannfeldt. These species were thus classified as "non-psilocybian." *P. fontinalis* Smith, *fraxinophilus* Smith, *guttulatus* Bresadola and *phalaenarum* (Fr.) Quélet were also included as "non-psilocybian" since there were no reports alleging hallucinogenic effects from these species (Ola'h 1969; Ola'h 1970).

Since the completion of Ola'h's monograph, additional studies have been reported on the chemistry of *Panaeolus* species. Psilocybin has been detected (0.08 percent dry weight) in an Italian collection of *P. retirugis* (Fiussello & Ceruti Scurti 1971-1972). Psilocybin has also been detected in Italian collections of *P. foenisecii* (one of two samples), *subbalteatus* (one sample) and *campanulatus* (one sample) (Fiussello & Ceruti Scurti 1972). Furthermore, psilocin has been detected in two Italian collections of *P. cyanescens* and psilocybin in one of these (Fiussello & Ceruti Scurti 1972). Mycelia and cultivated carpophores of Italian *P. subbalteatus* have been shown to be capable of producing psilocybin (Ceruti Scurti, Fiussello & Jodice 1972). One Italian collection of *P. gutiulatus* and *P. sphinctrinus* lacked psilocybin and psilocin (Fiussello & Ceruti Scurti 1972) and a collection of Czechoslovakian *P. campanulatus* was devoid of these indoles (Semerdzieva & Nerud 1973). Finally, an additional sample of *P. foenisecii* from Quebec was reported to be positive for psilocybin, and although a sample of carpophores of this species from Washington was determined to be devoid of psilocybin, this indole was detected in carpophores of *foenisecii* front Indiana (0.17 percent dry weight) (Robbers, Tyler & Ola'h 1969).

Since *P. venenosus* was known only, sometimes in great numbers, from mushroom-growing houses in New York, the "problem of its origin or occurrence in the wild state" was unresolved (Levine 1919). *P. venenosus* Murrill has been determined to be conspecific with *P. subbalteatus* (Berk. & Br.) Sacc. (Ola'h 1970; Singer & Smith 1958a), but the true identity of *P. semiglobatus* Murrill has been a mystery. Despite the fact that type material was described as *Campanularius semiglobatus* Murrill from New York (growing on manure in 1910 in Murrill's garden) (Murrill 1911; Saccardo & Trotter 1925), and that this species was later cited as occurring in Virginia (Murrill 1920), contemporary mycologists seem to have been unaware of these reports and suggested the causative species of the intoxication described by Douglass (1912) may even have been a *Stropharia* (Heim 1958; Ola'h 1970; Tyler & Smith 1963). The type material was thus obtained, examined microscopically by Ott and the author and determined to be *P. subbalteatus*. A professional mycological determination was then kindly provided by Guzmán stating that *P. semiglobatus* is conspecific with *P. subbalteatus*. Although *P. subbalteatus* may have a rubescent tinge (hence once even described as *P. rufus* Overholts), it is quite variable in color and morphology (on one occasion even cited as *P. variabilis* Overholts). Some strains mimic *P. papilionaceus*. Although various authors still refer to this "butterfly" *Panaeolus* as a distinct species (Ceruti Scurti & Bianco 1973; Guzmán 1972), Ola'h (1970) regards *papilionaceus* to be conspecific with *P. campanulatus*. The single citing of psilocybin in *campanulatus* by Fuissello and Ceruti Scurti (1972) has not yet been verified and it is certainly possible that the collection may have contained more than one species. Thus there is great probability that at least some intoxications attributed to *P. papilionaceus* or *P. campanulatus* were actually due to *subbalteatus* or other closely related species such as *sphinctrinus*.

The true identity of *P. ovatus* Cooke & Massee remains unknown. The only researchers to have studied the problem seem to be Aberdeen and Jones (1958) who state that "a detailed examination of *Panaeolus ovatus* Cke. & Mass. showed it to lie closely related to, and possibly identical with *Anellaria sepulchralis* (Berk.) Singer which is generally considered edible." *A. sepulchralis* is believed by Ola'h (1970) to be identical with *Panaeolus phalaenarum* (Fries) Quélet for which no chemical studies have been reported. It is possible that Aberdeen and Jones collected *P. phalaenarum* rather than *ovatus*, for *phalaenarum* had been cited from Australia in *Grevillea* even before the original description of *ovatus* (Cooke 1889). A more recent description of *ovatus* by Cleland (1934) is still insufficient in microscopic detail to be useful in distinguishing between the two species. The problem is further complicated by the fact that *A. sepulchralis* may be conspecific with *P. antillarum* (Fr.) Dennis rather than *P. phalaenarum*, if these latter two species are really distinct (Guzmán 1972). It may very well be that *Panaeolus cyanescens* was the cause of at least some of the intoxications attributed to *P. ovatus*. It was only quite recently, in fact, that the presence of *P. cyanescens* in Australia was first noticed (Hall 1973) and now it is known to be widespread there (Southcott 1974).

The biosynthesis of psilocin and psilocybin are enzyme mediated and the enzymes involved would be expected to have both genetic and environmental regulation. From the limited data available in case reports, chemical studies and metabolic considerations pertaining to psilocin (to be discussed in the next section), it appears that the frequency of genes allowing psilocin and psilocybin biosynthesis within some *Panaeolus* species, such as *foenisecii* and *sphinctrinus*, may vary greatly from one population to the next, whereas for other species such as *cyanescens* the complex of psilocybian alleles appears to be relatively stable and consistent. *Panaeolus* has long been a difficult problem for the fungal taxonomist and under the classification by Ola'h (1970) there are notable inconsistencies. The genus is basically divided into two subgenera: *Eu-Panaeolus* and *Pseudo-Panaeolus*. But even in the "true" *Panaeolus* there are species without pleurocystidia such as the "psilocybian" *subbalteatus*, the "latent psilocybian" *sphinctrinus*, and the "non-psilocybian" *acuminatus* as well as species with these facial cystidia such as the "psilocybian" *ater* and the "latent psilocybian" *fimicola*. In the "false" *Panaeolus* there are species such as the "psilocybian" *cyanescens*, "latent psilocybian" *foenisecii* and "non-psilocybian" *semiovatus*.

A more recent classification by Guzmán (1972) based on microanatomical characteristics, recognizes four subgenera. A chemotaxonomic classification, nevertheless, might be of greater utility in view of modern interest in psychoactive fungi. It is thus proposed that those *Panaeolus* species which are capable of synthesizing psilocin and/or psilocybin be considered as belonging to Section *Copeladia* Pollock, *sectio nov.* of the genus *Panaeolus* (Fries) Quélet. This section includes species with various probabilities of possessing these 4-hydroxytryptamine derivatives: a) high probability - *cyanescens* (Berkeley & Broome) Saccardo, *cambodginiensis* Ola'h & Heim and *tropicalis* Ola'h; b) intermediate probability - *subbalteatus* (Berkeley & Broome) Saccardo and *ater* (Lange) Kühner & Romagnesi; and c) low to moderate probability - *africanus* Ola'h, *castaneifolius* (Murrill) Smith, *fimicola* (Fries) Quélet, *foenisecii* (Fries) Kühner, *microsporus* Ola'h & Cailleux, *sphinctrinus* (Fries) Quélet, *retirugis* (Fries) Quélet and *campanulatus* (Fries ex Linnaeus) Quélet. Those species with a high probability of possessing 4-substituted indole hallucinogens comprise Guzmán's subgenus *Copelandia*, whereas those which appear to have "intermediate" probability of containing these compounds fall into his subgenus *Panaeolus*. Those with low to moderate probability of producing hallucinogenic constituents are found in Guzmán's subgenera *Anellaria* (*africanus*), *Panaeolina* (*foenisecii*) and *Panaeolus*. Species not included in Section *Copelandia* would be expected to have very low or unknown probability of producing psychotropic 4-substituted indoles.

The bluing phenomenon and other metabolic considerations

"The blue color of the sclerotia and of the base of one single specimen" of *Panaeolus subbalteatus* appeared "to be of the same nature as the bluing in *Copelandia cyanescens* (Berk. & Br.) Sing." (*Panaeolus cyanescens*) "and the bluing *Psilocybes*" (Singer & Smith 1958a). Thus Singer and Smith surmised:

> If this assumption is correct, it must become quite clear that a direct or indirect relation must exist between the bluing capacity of a species and its capacity to provoke cerebral mycetisms. On the basis of this hypothesis it is actually possible to predict which genera and species might be significant for the research on cerebral mycetisms of the type represented by *Panaeolus subaltetus* [sic] and *Psilocybe caerulescens*.

It seems that Guzmán may have contributed to the origin of this bluing hypothesis, for Singer (1958) related "that there are a *Psathyrella* and copelandias from Santa Cruz which Guzmán, who collected them there, is inclined to think may be hallucinogenic." While *Psathyrella sepulchralis* Singer, Smith & Guzmán does not blue and was probably confused by some Zapotecs with *Psilocybe zapotecorum* (Singer, Smith & Guzmán 1958). Singer (1962) soon began to refer to the *Copelandia* (*Panaeolus cyanescens*), an ardent bluer, as "apparently hallucinogenic."

While the bluing reaction has not been studied in hallucinogenic mushrooms *per se*, a number of studies shed light on this phenomenon. Blaschko and Levine (1960a) found that the gill plates of the mussel *Mytilus edulis* Linnaeus possess an enzyme which readily converts psilocin to a blue product with the consumption of oxygen. This reaction occurs more rapidly with psilocin (4-OH-*N*,*N*-DMT) than with either its 6-hydroxy isomer or 5-

hydroxy isomer bufotenin. Since it was known that both the bivalve molluscan enzyme and ceruloplasmin, a copper containing oxidase of mammalian plasma, could utilize 5-hydroxytryptamine (serotonin) as a substrate, Blaschko and Levine (1960b) performed a comparative study. Both the *Mytilus* enzyme and ceruloplasmin from pig plasma convert psilocin and 4-hydroxytryptamine to a blue product, whereas bufotenin and its 6-hydroxy analog as well as serotonin, 6-hydroxytryptamine and 7-hydroxytryptamine are oxidized to brown pigments. Some important differences in the two enzyme systems were also noticed. For instance, whereas the mollusk enzyme could also utilize 4,5 and 7-hydroxytryptophan (the former yielding a blue pigment and the latter two brown pigments), these amino acids were not suitable substrates for porcine ceruloplasmin.

When Horita and Weber (1961a) were studying the dephosphorylation of psilocybin by alkaline phosphatase of various mammalian tissues, they discovered that in some of their preparations, especially heart and kidney, the liberated psilocin was oxidized so rapidly to a blue metabolite that they were unable to measure the formation of psilocin. By inhibitor studies and the tissue distribution of the oxidase activity, they were able to conclude that monoamine oxidase, an enzyme very important in serotonin and dopamine metabolism, was not the enzyme acting on psilocin.

Weber and Horita (1963) then determined that cytochrome oxidase, a mitochondrial enzyme, is responsible for the rapid oxidation of psilocin by tissue homogenates. Using a preparation of cytochrome oxidase derived from pig heart, these investigators found that while psilocin is oxidized to a dark blue product and the synthetic hallucinogen 4-hydroxy-*N,N*-diethyltryptamine to a bluish-green metabolite, 4-hydroxytryptamine becomes a blackish-brown pigment. Bufotenin, 5-hydroxytryptamine and 5-hydroxytryptophan are converted to brown compounds. Furthermore, "the 4-hydroxyindoles are consistently better substrates for the cytochrome oxidase than are the 5-hydroxyindoles" (Weber & Horita 1963).

Kalberer, Kreis & Rutschmann (1962) synthesized ^{14}C-psilocin and studied its *in vivo* metabolism in rats. After oral or intravenous administration of 10 mg/kg psilocin, at least 80 percent of the radio-psilocin was excreted during the first 24 hours. About 25 percent of the psilocin was passed unaltered in the urine and only about 4 percent underwent demethylation and subsequent oxidative deamination to 4-hydroxyindoleacetic acid. The largest portion of urinary metabolites were unidentified non-glucuronide hydrophilic substances.

In vitro studies with purified calf intestinal phosphatase and homogenates of brain, heart, kidney, liver and small intestine from various mammalian species have shown that psilocybin is an excellent substrate for alkaline phosphatase (Horita & Weber 1961b). Additional studies have shown that psilocybin is rapidly dephosphorylated *in vivo* in mice (Horita & Weber 1962). Furthermore, pretreatment with β-glycerophosphaite, a competitive substrate for alkaline phosphatase, not only diminished tissue concentrations of psilocin but also "reduced the intensity of the reaction as compared to normal mice treated with psilocybin (Horita & Weber 1962). Parallel measurements of psilocybin tissue concentrations were not attempted due to lack of a suitable assay (Horita 1975). Depression, exophthalmos, piloerection and some hindleg ataxia were noted as major symptoms of the psilocybian reaction in mice. These studies along with some ancillary observations, such as the lipid solubility of psilocin being greater than that for psilocybin, strongly suggest that psilocin is the pharmacologically active metabolic form of psilocybin (Horita 1963).

Returning to the bluing phenomenon, Gilmour and O'Brien (1967) noticed that a subfraction of rat brain mitochondria produced a dark blue color in the presence of psilocybin with prolonged incubation and that oxygen was not required. This as pointed out by Levine (1967) resulted from the action of a phosphatase liberating psilocin and a subsequent oxidation by the ferric ions present, for among other considerations the chelating agent EDTA markedly inhibited the production of the blue color. Bocks (1967a) discovered that *para*-diphenol oxidase (laccase) derived from the fungus *Polyporus versicolor* is capable of oxidizing psilocin to a blue product which has a similar ultraviolet spectrum to the compound obtained by ferric chloride oxidation of psilocin.

Laccases, first isolated from lacquer trees and responsible for the blackening of lacquer tree juices, possess certain properties similar to ceruloplasmin ("animal laccase"). For instance, they are copper-containing and share many substrates such as *para*-phenylenediamine and hydroquinone (Peisach & Levine 1965). An unusually stable laccase has been isolated from a mushroom known as *Russula foetens* (Gregg & Miller 1940). In addition to acting on usual substrates, this *Russula* enzyme has been demonstrated to catalyze the oxidation of an inorganic salt, potassium ferrocyanide (Gregg & Miller 1940). Laccase is essentially a *para*-diphenol oxidase in contrast to the copper containing phenolase complex (tyrosinase), which not only is responsible for *ortho*-hydroxylation of phenols but also is an *ortho*-diphenol oxidase (Mason 1955). Furthermore, *para*-diphenol oxidases are blue copper proteins in which there is a valency change in the copper from 2^+ to 1^+ during the oxidation of substrates, whereas *ortho*-diphenol oxidases are colorless with the copper remaining at 1^+ valence and thus suggesting a different mechanism of action (Bocks 1967b). Nevertheless, there is some overlapping of substrate specificity. The *Russula* laccase as an example may oxidize catechol "at nearly the same rate as *p*-phenylenediamine and hydroquinone" (Gregg & Miller 1940). *Para*-cresol and catechol have been routinely used to measure the aerobic oxidation of monohydric and *o*-dihydric phenols by tyrosinase. It is noteworthy that these two activities have been partially separated in enzyme preparations derived from the common commercial edible mushroom (Adams & Nelson 1938; Mallette & Dawson 1949; Mallette *et al*. 1948) (*Psalliota campestris* as it used to be called in Europe, *Psalliota bispora* as it is now called in Europe and *Agaricus bisporus* as it is now usually called in the Americas).

Furthermore, a mycelial extract of the commercial mushrooms was shown to catalyze the oxidation of *p*-phenylenediamine at about twice the rate as that of catechol and an extract from carpophores of this mushroom oxidized catechol but not *p*-phenylenediamine. Rhizomorphs ("stings of hyphae which transport substances from the absorbing mycelium to the fruitbodies") catalyze the oxidation of both *p*-phenylenediamine and catechol, the latter more rapidly (Lindeberg 1950). It was suggested that the oxidation of the catechol was partly due to lacaase and partly to polyphenoloxidase (tyrosinase). Thus the mycelia may produce laccase and the carpophore a tyrosinase, "whereas in the rhizomorphs a mixture of both enzymes is formed" (Lindeberg 1950).

Adventitious browning is well known to occur in the flesh of certain ripe fruits (such as apples, pears and avocados) and some vegetables (such as eggplant) as well as in the hyphae of mushrooms following injury during harvesting, storage or preparation for the table. This rapid browning seems to result from the oxidation of endogenous phenols catalyzed by enzymes having laccase and phenolase activity, but other enzymes such as peroxidases and catalases, which require the presence of hydrogen peroxide for activity, might also make a contribution (Mason 1955). The bluing reaction most likely is mediated by the same enzymes.

Singer (1948) first observed that the bluing reaction of *Stropharia cubensis* Earle could be enhanced by the use of metol (*para*-methylaminophenol). He later stated that "a chemical character which accompanies the bluing phenomenon is that of metol, which gives a constant strongly positive reaction with the context of the stipe in the bluing psilocybes, becoming deep purple after a few minutes" (Singer 1958). Although the "metol test" later became popularized for the rapid identification of psilocybian mushrooms (Enos 1970), it is entirely nonspecific. I have applied small aliquots of a fresh saturated solution of *p*-methylaminophenol sulfate to sections of the brown and white varieties of commercial *Agaricus bisporus* and observed the rapid development of purple staining. A simultaneous experiment was run employing *p*-aminophenol sulfate which promptly produced dark brown staining. After about 5-10 minutes, a purple tinge could be observed on these darkened mushroom pieces. Both compounds eventually produce a blackish-brown discoloration. Controls brown very slowly and the color is not as intense. *Para*-aminophenol is a known laccase substrate (Peisach & Levine 1965) and *p*-methylaminophenol must also serve as a substrate for such phenol oxidases.

Modern use of Panaeolus mushrooms

The recreational and spiritual use of psilocybian mushrooms has become a worldwide transcultural phenomenon (Pollock 1975). Although much new information has been gathered on the use of cyanescent *Stropharia* and cerulescent *Psilocybe* species, the present discussion will focus primarily on *Panaeolus*.

The most widely utilized *Panaeolus* appears to be the coprophilous *P. cyanescens*. This predominantly tropical species, commonly called a "copelandia" and originally described from Ceylon, is also known from the Philippines (*Copelandia papilionacea* sensu Bresadola), Indonesia, Australia, Cambodia, Malagasy Republic, Florida (*Campanularius westii* Murrill), Mexico, Jamaica (*Panaeolus anomalus* [Murrill] Sacc. & Trott.), Hawaii, Brazil, Bolivia and even as far north as France and Italy. The author has received personal communications suggesting the use of this species in Chiapas, where *Panaeolus cyanescens* is a common psilocybian species. By the fall of 1972, it had become obvious to college students that psilocybin mushrooms were abundant in Florida (Kimbrough 1975) and word-of-mouth stories told of fraternity parties with bushel-basket quantities of magic fungi. With a widespread reputation that "Gainesville is Kingsville" for psilocybin mushrooms, it is entirely possible that some mycophagists sampled *Panaeolus cyanescens* in addition to the ubiquitous *S. cubensis* Earle. By 1972, the use of this cyanescent *Panaeolus* had become well established in the Hawaiian Islands (Pollock 1974) and it appears that other psychoactive fungi might occasionally be employed there as well. For instance, *Panaeolus tropicalis*, a species reported on dung of cattle and wild animals from Cambodia, the Republic of Central Africa and Mexico, has now also been identified from Hawaii (Rhoades 1975). During recent field studies in the Pacific Northwest, it came to the author's attention that a few years ago entrepreneurs in Hawaii exported some small psilocybin mushrooms (probably *Panaeolus*) on dry ice to an eagerly awaiting California street market. It seems that this psychotropic merchandise had spoiled and lost activity due to delays in unloading and distribution. Although knowledge that drying is the best way to preserve these mushrooms had not generally reached the public, folk knowledge that the mushrooms could be stored for short periods of time in honey was available in Hawaii and elsewhere. Thus, the mushrooms were allegedly exported in honey with satisfactory results, except perhaps for the taste which was quite unpalatable to the consumer from whom this information was elicited.

Bali, Indonesia has gained a worldwide reputation as an exotic mushroom paradise. Almost three years ago a former Peace Corps worker who had traveled to Bali recounted to the author her experience after a psychedelic mushroom omelet, the mushrooms having been purchased from native children on the beach. Although Heim (1973) suspected the use of *Panaeolus cyanescens* in Bali after a report from a Dutch correspondent, no specimens were available. Recently, however, a sample from Bali arrived in Mexico containing carpophores of a yet unidentified *Conocybe* species and *Panaeolus cyanescens* (Ott 1975). The Caribbean has also become quite a mushroomic Elyseum. In Jamaica, for example, island inhabitants eagerly collect and dry magic fungi to brew in delectable teas for personal use and to sell to mycophilic tourists. *Panaeolus cyanescens* is certain to be one of the species utilized.

"Copeladias" are now often collected, utilized and sometimes even sold for their psychedelic effects in Australia, where users refer to them as "blue meanies" (Southcott 1974). This name may refer not only to their bluing, but also to their potency. It has been said "that about six of the blue meanies were enough for a good trip, and they were sometimes eaten straight, or in curry, etc." (Southcott 1974). A case has been cited in which a 17 year old female "with a history of use of cannabis and LSD, on one occasion, about 1971, partook of some *Copelandia cyanescens* obtained in the vicinity of Adelaide. She became frightened when her hallucinatory attack came on and sought medical attention. She stated that she thought she was a banana and somebody was skinning her" (Southcott 1974). Despite the growing use of *Panaeolus cyanescens*, it appears that "Gold Tops" (a composite term for *S. cubensis* Earle, *Psilocybe subaeruginosa* Cleland and presumably also *Psilocybe collybioides* Singer and Smith [Southcott 1974]) are more widely employed in Australia (Hall 1973; McCarthy 1971; Southcott 1974).

Panaeolus cambodginiensis, another coprophilous species, had been known only from Cambodia. Material originating from Colombia in June, 1974 had been tentatively identified by Ola'h as the same species (Pollock 1975). Guzmán has now established the identity of this species as *cambodginiensis*. With mushroom consciousness as high as it is in Colombia, chances are good for the occasional use of this fungus.

Panaeolus subbalteatus was first described as collected in a tare field in Apethorpe, England in 1860 and was next observed in the botanical garden in Brussels, Belgium. Although this coprophilous and occasionally terricolous species had been noted from additional sites in Europe. Massachusetts, Michigan, Missouri, Ohio, Ontario, New York, Quebec and Washington; as well as from Mexico, Argentina, Japan and Africa, no deliberate non medical use of this fungus for the alteration of consciousness has been reported. In the last few years many people in Oregon have become very much aware of the presence of psilocybian mushrooms (Ott in publication; Weil 1975). Liberty Caps have become well known on rich pasture land soil, for it has been observed by the author that herbarium collections from all over Oregon were identified by Alexander Smith as *Psilocybe semilanceata*. It is possible, however, that Smith was confusing this species with *Psilocybe pelliculosa* (Smith) Singer and Smith. Unfortunately, disrespectful mycophagists have stolen all of this material from the herbarium in question, and it is not possible to verify his identifications. Another species widely employed is a *Panaeolus* which occurs not only in the garden (on manure) but also on composting hay piles. Mycologists in Oregon examined such specimens and identified them as *Panaeolus subbalteatus* (Denison 1975; Rhoades 1975). It seems that there is another coprophilous *Panaeolus* which is much less frequently employed in Oregon. Users had supposedly been ingesting up to 250 carpophores of a species which was later determined by chemical analysis to contain traces of psilocybin and identified by Guzmán as *Panaeolus sphinctrinus* (Ott 1975). This latter species is cosmopolitan. It is probably ingested deliberately in Colombia where unfortunately like elsewhere the standard cliche is "if it grows on cow dung, it is hallucinogenic." A trial by the author of a soup containing 50 specimens of *P. sphinctrinus* gathered in Texas was without noticeable psychic effects, a sample of this collection later having been identified positively by Guzmán.

Although indications are that *Paneolus campanulatus* may be generally "inactive," it seems to be employed in southern California where 40 to 60 little brown lawn mushrooms are said to constitute a dose. Lawn inhabiting *Panaeolus* is usually *foenisecii* but the identity of a sample of such material obtained by the author has been determined by Guzmán to be *P. campanulatus* sensu Hora. The extent of its use elsewhere has not yet been ascertained.

Panaeolus ater, originally described from Denmark as a variety of *P. fimicola*, has also been reported elsewhere in Europe and from the East Indies. Alaskan herbarium material, one collection of which had been tentatively identified by Kempton as *Panaeolus ater*, was obtained by the author for further study. Guzmán has now keyed out not only a 1963 south-central Alaskan collection from a grassy area in mixed woods but also another collection from Anchorage as *Panaeolus ater*. No bluing was noted when the Alaskan specimens of *ater* were collected (in contrast to *P. ater* from the East Indies). Thus, aside from being rare, the Alaskan strains may be inactive. Furthermore, although authenticated *P. foenisecii* and *P. sphinctrinus* were found by the author to be quite common on lawns and soil enriched with horse dung in Anchorage, there has been no indication of attempted use of these inconsistently psilocybin-containing species by the Alaskan populace. Nevertheless, it seems that psilocybin mushrooms are sometimes employed even as far north as Alaska since the author was told of an occasion in which dried, yellow-colored magic mushrooms sent from Louisiana were enjoyed there. The mushrooms in that instance presumably were *S. cubensis*, a species so plentiful in Louisina and other Gulf Coast states that it served as the basis for a bogus field guide (Ghouled 1972). That publication, like others (Enos 1970; Fisher 1973) of its kind, was filled with misinformation. Ghouled (1972) even referred to a photograph of cubensis primordia as depicting the "young state of *P. subbalteatus*, choice and edible." Furthermore, Jacobs (1975) who suggests in a medical journal that "Mississippi and adjacent states are rapidly receiving a reputation in the drug culture as the 'mushroom capital' of the United States," believes that *Panaeolus subbalteatus* is "the second native hallucinogenic mushroom" in Mississippi. He based his identifications and much of his misinformation on Ghouled's misleading guide.

It has been alleged by Sanford (1972) that "a rather well known mycologist in the Boston area has seen *Panaeolus papilionaceus* deliberately gathered in both Maine and Louisiana. Interestingly enough, in the case of New England, it was thrifty farmers taking advantage of an opportunity to get 'drunk for nothing,' while in Louisiana the gatherers were rather more modern sophisticates looking for a psychedelic thrill." The psychoactive mushrooms eaten in Louisiana probably were not *Panaeolus* at all but rather *S. cubensis*, whereas in Maine *Panaeolus* does seem to be employed. Blackington (1958) describes an experimental trial of *Panaeolus papilionaceus* by Brother Bacon of Norway, Maine to achieve a "mental jag." The results of the first "tasting were so unusual, Mr. Bacon ate them many times again." It has also been reported in a Maine newspaper that a group of French Canadian fishermen consumes *Paneolus campanulatus* for its intoxicating properties when they fish in Maine, the identification having been provided by a state botanist (Schultes 1974). Bacon's amateur identification was based on Mellvaine's *One Thousand American Fungi* which is entirely inadequate for *Panaeolus* identification and it is not known what guide was employed in the latter identification. It is noteworthy that Wasson (1974), who was, of course, interested in the use of *Panaeolus* in Maine, could not extract a letter from Blackington. Most likely the *Panaeolus* employed there is *subbalteatus*, but other species such as *sphinctrinus* and *fimicola* are possibilities as well.

The trip beyond ecstasy, psycho-mycological frontiers

When a mind-altering substance is suddenly unleashed on a population already accustomed to using an array of psychoactive compounds, mass media may foster a rampant escalation of use. Such was the case with methaqualone, once heralded as a "downer with a difference," for "luding out" rapidly became a popular pastime in the United States (Agar 1972). The overall recreational use of methaqualone, however, soon declined. The use of psilocybian mushrooms for ecstatic experiences, in contrast, generally continues to become incorporated into the fabric of modern society.

When Hofmann traveled to Huautla de Jiménez, where these mushrooms have been traditionally employed since ancient times, the renowned *curaudera* María Sabina enthusiastically accepted his offering of manufactured psilocybin (Kreig 1964), but after a synthetic dose she did not seem to prefer the tablets to the mushrooms themselves (Wasson 1976). Mass media reports have greatly stimulated public consciousness of these fungi. But in technologically advanced societies, where psychotropic substances of all sorts can be purchased illicitly (usually in adulterated form) from street markets, genuine hallucinogenic fungi have usually not been available. Although wild psilocybian mushrooms are much more widespread than ever appreciated, interested persons have by and large gradually had to learn how to recognize the locally available species. Tourists have been traveling to Huautla for a long time, and the resemblance of Liberty Caps to *Psilocybe mexicana* Heim could not have gone unnoticed in such areas as British Columbia.

Misinformation has surrounded psychedelic mushroom use in British Columbia as well. Liberty Caps have been employed there since the early 1960's, despite later misnomers that in Canada "several varieties of psilocybin mushrooms" growing untended "would appear" to "have been ingested by only a few exceptional experimenters" (Canadian Report 1973). From Vancouver to the Queen Charlotte Islands the use of Liberty Caps has become such an integral part of subcultural living that the season is announced in the popular press (Oakenbough 1974). Even a seven year old girl in Vancouver was observed by the author to maintain her own "stash." She had developed a fondness and respect for these mushrooms plus a tremendous inquisitiveness toward them. Whenever adults would employ Liberty Caps (the usual dose being 20-25), she would usually eat one or two and claimed to experience a mild effect.

The identity of the British Columbia Liberty Caps has been presumed to be *Psilocybe semilanceata* (Dawson & Morelli 1975). This identification may have been based on a public awareness publication (British Columbia Access 1972) which duplicated most of its material from Enos (1970) to serve as a hallucinogenic mushroom guide for British Columbia. From examination by Guzmán of collections in the fall of 1975, it has now been determined that Liberty Caps refer to two species, *Psilocybe pelliculosa* and *semilanceata*. Furthermore, field studies have now turned up additional species in use such as authentic *Psilocybe cyanescens* in Washington. The annulated "*cyanescens*" referred to by Weil (1975) actually represents a new species.

Psychomycological field studies are needed in other areas of the world as more species remain to be discovered. Since *Panaeolus texensis* specimens are no longer available (Smith 1975) and the Latin description is insufficient in detail to be useful, this species entity must be disregarded. Nevertheless, there are species of *Panaeolus* and other psilocybian genera which remain in need of chemical analysis. Although strain differences in alkaloid production have already been observed chemically, there may be differences in the spectrum of biosynthetic alkaloids produced by different species. Such differences may well be important psychopharmacologically and it would be erroneous to presume that the psychotropic actions of psilocybian fungi can be predicted entirely based on studies with pure psilocybin or psilocin. Just as additives to new world hallucinogenic preparations may be important (Schultes 1972) so might other constituents present in the mushrooms. So little clinical study has been attempted comparing the psychoneurophysiologic effects of different psilocybian species (Stein 1959; Stein, Closs & Gabel 1959), that this area of investigation is virtually unexplored.

Although psilocybin is generally considered to be equipotent to psilocin on a molar basis, this actually may not be true. Wolbach, Miner & Isbell (1962) compared the effects of psilocin and psilocybin after intramuscular injection in human subjects, autoclaving the compounds in a solution containing vitamin C prior to administration. It was believed that the "addition of Vitamin C effectively prevented the alteration of psilocin to a compound with a deep-violet hue." Vitamin C, however, has been shown to reduce the blue oxidation product of psilocin (possibly a dimeriquinone) to a colorless compound (Bocks 1967a). Thus, it is unknown what the dosages of psilocin employed by these investigators actually were.

While psilocin, psilocybin, mescaline and LSD are generally considered to produce the same clinical manifestations in people, there are probably important neuropharmacologic differences which have yet to be explored. It is known, for instance, that while psilocybin, LSD and muscimol increase body temperature toward normal in mice pretreated with reserpine, mescaline causes a further decrease and ibotenic acid has no significant effect (Waser 1967). LSD (300 µg/kg i.v.) has been shown in unrestrained rats to increase blood flow to the frontal and parietal lobes as well as to the cerebellum (Goldman *et al*. 1975a). Furthermore, whereas in rats delta-9-tetrahydrocannabinol (1 mg/kg i.v.) significantly decreases blood flow to the cerebellum, hypothalamus, basal ganglia and dorsal hippocampus (Goldman *et al*. 1975b), the only significant effect of psilocybin (10 mg/kg i.v.) on brain blood flow was a decrease to the dorsal hippocampus (Fischer 1975). Data on mescaline are not yet available (Fischer 1975). Although it is suggested that autoradiographic studies with ^{3}H-LSD "strengthen the hypothesis that the action of LSD in the brain is linked in some way to serotonergic neurons" (Diab, Freedman & Roth 1971), more extensive studies have been done with ^{14}C-psilocin. No correlations could be found between the distribution pattern of ^{14}C-psilocin in rat brain "with the numerical nerve and glial cell density, the volume cell density, the capillary density, the contents of oxidative enzymes, the uptake of labelled amino acids, the lipid contents and other patterns known through chemical or histochemical studies" (Hopf & Eckert 1969). Psilocin uptake is low in the hypothalamus (serotonin rich) but very high in the neocortex (serotonin poor). Futhermore, it is high enough in the serotonin-rich hippocampus, an important part of the limbic system, to suggest that "a main site of action on this structure could explain some of the behavioral effects" of psilocin (Hopf & Eckert 1969). Hallucinogenic substances would reasonably be expected to have multiple sites and mechanisms of action. There is already some evidence that in addition to central serotonergic pathways, dopaminergic pathways may be involved in the complex action of LSD (Horita & Hamilton 1973; Pieri, Pieri & Haeferly 1974; Roszell & Horita 1975; von Hungen, Roberts & Hill 1974). Dubansky and Vyhnankova (1967) administered psilocybin to healthy volunteers and to brain-damaged patients. They observed that complex hallucinations and other visual psilocybin manifestations tended to be almost completely suppressed in persons with lesions involving central optic pathways. In contrast, while the absence of complex hallucinations was observed in patients with brain lesions but intact central optic pathways, other visual manifestations of psilocybin were observed. No studies have yet been attempted to determine what central nervous system pathways are actually essential for other manifestations of psilocybin intoxication such as the prominent tendency toward laughter and the frequent yawning.

Field observations are that psilocybian mushrooms are often employed with *Cannabis* species and/or alcoholic beverages. Furthermore, the author has observed the concomitant use of *Psilocybes* with *Amanita muscaria* in British Columbia and the Pacific Northwest. The pharmacologic interaction between psilocin or psilocybin and other psychoactive compounds such as delta-9-THC, ethanol, ibotenic acid and muscimol has not yet been investigated. Such studies would certainly be worthwhile not only because these compounds are often employed together but also because of the great potential for obtaining important new information on central nervous system neuropharmacology.

There may well be mushroom hallucinogens of an entirely different chemical nature than the tryptamines and isoxazoles. Numerous species in various genera have reputations, albeit some most obscure, of being psychoactive (Heim 1963). One notable example is *Pholiota spectabilis* (Fries) Kummer, in North America now usually designated as *Gymnopilus spectabilis* (Fr.) Smith. In 1942, a Cleveland, Ohio resident "had taken a few nibbles from a mushroom that she found" in the woods. Later she experienced "the most glorious visions of color and sounds of music, but with no feeling of discomfort whatever" (Waters 1965). The hallucinations soon passed and this victim of mycetismus "added that if this were the way one died from mushroom poisoning, she was all for it." The fungal identification seems to have been reliable and this species had been reported from Japan as producing such effects (Romagnesi 1964). The Japanese name for this fungus is even *o-waraitake* ("big-laughing mushroom") (Sanford 1972; Wasson 1973). A mycetism case involving three persons occurred in Boston in 1966, and indole derivatives other than psilocin and psilocybin were reported to occur in a sample of the *spectabilis* (Buck 1967). It was later determined that a false positive reaction for indoles was produced by *bis*-noryangonin present in this spectacular species (Hatfield & Brady 1969). Such styrylpyrones are widely distributed in *Gymnopilus* species (Hatfield & Brady 1971), some of which are "edible." Thus the psychoactive principles in *spectabilis* remain unknown.

Although the natural distribution of fungal psychotropogens is still largely unknown, even less is known about their neuropharmacologic mechanisms of action. The natural tendency of human beings to partake of "mind-altering" substances is so well documented (Efron, Holmstedt & Kline 1967: Schultes & Hofmann 1973) that one can easily perceive why arbitrary legislation and enforcement procedures are entirely useless in preventing such social pharmacological behavior in modern societies. The sanctioning of some modulators of "escape" such as ethanol with the disapproval, or legal taboo, of other more efficacious substances is sheer nonsense. When a human being experiences a drug induced alteration of consciousness there occurs a simultaneous change in psychic free energy, thermal energy and entropy. A chemical reaction is accompanied by the liberation or absorption of heat energy (enthalpy) and a change in entropy. Entropy (ΔS) pertains not only to the randomness of the system but is the final form into which heat energy dissipates. This change in the "state of chaos" (ΔS) together with the change in enthalpy (ΔH) results in a change in free energy (ΔF). These changes can be accurately measured for chemical reactions in vitro (Kitzinger & Benzinger 1960), but the complex electro-chemical changes which occur as one experiences a chemical catalytic alteration of consciousness are not accessible to such measurement. The "escaping" tendency of matter and other forms of energy toward entropy is so well known thermodynamically that an attempt to maintain a single homeostatic state of consciousness would have to be an entirely unnatural act. Exploration of the potential usefulness of alternate states of consciousness has certainly begun (Drug Abuse Council 1975), but is still in its infancy.

One obvious promising field for use of hallucinogens as mediators of pathways to alternate states of consciousness is, of course, medicine. It has been proposed both in Europe (Leuner 1968) and the United States (Fischer & Goldman 1975) that psilocybin or a related substance be used in psychotherapy rather than mescaline or LSD. While LSD may be extremely useful (Grof 1975), clinical observation from well over a thousand controlled hallucinogenic drug sessions is that psilocybin is shorter acting, seems to produce very few adverse reactions, is associated with fewer flashbacks and is accompanied by less post session depression than the hallucinogens LSD and mescaline (Fisher & Goldman 1975; Leuner 1968). Although psilocybin is substantially more efficious than LSD or mescaline, various other hallucinogens as well as natural dosage forms of these compounds deserve such testing.

The efficacy of psilocybin is further demonstrated by the paucity of adverse reactions occurring from the use of psilocybian mushrooms. Although "bad trips" are occasionally reported from these fungi (McCarthy 1971; Stein 1958), they are much easier to manage than are those often produced by various synthetic street drugs. Although it was suggested that *P. candidipes* Singer & Smith may be "poisonous" rather than just hallucinogenic (Singer 1958), recent studies suggest that this is not the case (Ott 1975). Furthermore, Singer and Smith (1958b) not only allege that Imai (1932) reported cases of death caused by *S. caerulescens* Imai (later changed to *S. venenata* Imai for nomenclatural reasons) but also that this Japanese species is conspecific with Höhnel's Javanese species *subaeruginascens* and *aerugineomaculans*. *S. venenata* was not reported to have caused any deaths (Imai 1932) and is regarded as a hallucinogenic mushroom in Japan, no different essentially from any other Japanese psilocybian species (Matsuda 1960; Sanford 1972; Wasson 1973; Yokoyama 1976). There are no rumors in Japan of *venenata* being deadly (Yokoyama 1976) and its name is *shibiretake* ("benumbing mushroom"). Authentic *venenata* was kindly supplied by Hongo and Yokoyama and type material of *subaeruginascens* and *aerugineomaculans* was obtained for comparison. Microscopic examination by the author with McLain suggested that *venenata* is a distinct species. Although we must await definitive determinations by Guzmán to be sure, it appears that Singer and Smith were mistaken in all matters pertaining to the *venenata* problem.

Psilocybian mushroom use in Australia has generally reached socio-pharmacologic equilibrium. Although more fungal "abuse" cases are being detected now, there has been no additional legislation, and the phenomenon of psychoactive mushroom use in Australia has generally not changed over the last few years (Hall 1976). Although no additional psilocybian species have been reported from Australia, there is a white fungus being employed there that resembles the deadly *Amanita verna*. It is called "white frenzy" or "white death," but no deaths seem to have been attributed to its use (Hall 1976). In the United States, genuine psilocybian mushrooms and possibly extracts prepared from them are occasionally sold as street drugs to meet the tremendous demand. Such a practice may be expected to continue until duly licensed and inspected commercial sources of supply become available for distribution through legitimate channels to provide the consumer protection that is indicated. Although use of these fungi is still growing in the U.S., drug abuseologists and drug "scapegoaters" as discussed by Szaz (1975) cannot reasonably consider this phenomenon a major problem. Between July 1973 and June 1975, the DEA confirmed the psilocybin content of nine exhibits (one from Arkansas, one from Oregon, five from Louisiana, one from Missouri and one from Washington) and the psilocyn [*sic*] content of two exhibits from North Dakota (Johnson 1975), and in January 1975, PharmChem Labs (1975) reported the presence of psilocin in four street samples and both psilocin and psilocybin in another, sources noted from California and Oregon. These figures compare rather meagerly to 978 exhibits of LSD, 930 of PCP and 70 of "other" hallucinogens such as 4-bromo-2,5-dimethoxyamphetamine, the thiophene analog of PCP, etc. confirmed by the Drug Enforcement Administration for the fiscal year 1975 alone (Johnson 1975). In 1970, LSD constituted 9 percent of the total DEA analytical work load, whereas "all hallucinogens" (a category that includes the sympathomimetic but not hallucinogenic compound MDA) constituted 11 percent. By the end of fiscal 1975, confirmed LSD exhibits comprised 2 percent and "all hallucinogens" (including 25 MDA exhibits) comprised only 5 percent of their total analytical workload (Johnson 1975).

Psilocin or a suitable congener may well prove to be of great utility in psychoanalysis and psychotherapy. It may certainly be efficacious for therapy of opiate dependent patients, alcoholics and certainly abusers of street hallucinogens. The potential for detecting some organic brain lesions by the use of such compounds has also been observed (Dubansky *et al*. 1963), and their potential for assisting with the alert terminally ill should also be considered. Since LSD has already been shown to be of benefit in some of these patients, might not psilocybian mushrooms, with their tradition of use in medico-religious rites since ancient times, be a more natural, psychologically aesthetic medicinal sacrament in the preparation of these patients for a death with dignity?

Acknowledgments

The author is grateful for assistance from a great number of people in matters pertaining to various aspects of this project and is especially indebted to Professor Gastón Guzmán, Director of the Laboratory of Mycology, National Polytechnic Institute of Mexico and Jonathan Ott of the Institute of Biomedical Research of the National University of Mexico.

Turning topiary

On my travels in Mexico many years ago, last millennia in fact, I came across a psychoactive plant, known locally as 'the shepherdess', which was used by indigenous people for divination and healing. I was given the opportunity to try this foreign foliage and doing so had an incredible and entirely unexpected experience. Within moments of consuming the herb a strange sensation began seeping through my toes and fingertips and moved towards my core turning me rapidly into some kind of thorn bush. The metamorphosis spread quickly up my arms and legs, across my body and up to my head until I found myself completely transformed into a small spiky shrub. I was quite literally rooted to the spot and could not move.

Simultaneous to this, all the trees and all the plants, in fact every blade of grass across the large field within view, began laughing hysterically. Anything and everything before me that photosynthesised was in side-splitting fits and they were all cracking lines like "now you know what it's like to be a plant, ha, ha, ha", swaying back and forth, shrieking and howling with laughter. I didn't find this particularly funny though, because I was absolutely convinced of my transmutation, and furthermore believed it to be permanent. Oh how the plants laughed. Then a disembodied voice spoke. Loud, deep and stern. A woman's voice. She said something like, "you stupid humans think you run the show around here, you're so arrogant, but you haven't got a clue". And then she proceeded to lecture me on species-centrism and our lack of harmony with others on Earth. I was terrified and 'bewildered' - in the literal sense too - for although I had hypothetically reasoned that everything might be inherently conscious, I had never expected to be chastised by the spirit of Nature or publicly ridiculed by grass.

The experience, mercifully, only lasted ten minutes, and quickly subsided as the voice drifted away and I turned back into a slightly more aptly named *Homo sapiens* than before. The immediate psychological effects had gone, but the ontological shock remained indefinitely. I would say that this was my first serious shamanic experience with plant (or fungal) psychedelics[1], and since then I have never considered ecology in quite the same way as before.

Ecodelicately

So, this is my personal starting point for editing this special issue, but why *Ecopsychology* and the *Psychedelic Experience* anyway? Elsewhere (Krippner & Luke, 2009), I have indicated two simple reasons: that psychedelics may enhance the experience of Nature or, given that these substances readily occur outside of the lab, the consumer is therefore compelled to go into the wild to obtain them. But of course, psychedelic experiences and the encounter with Nature usually run much deeper than this, and may even lead to a direct communication with other species. When it does so it is often the same message, which usually runs a little like those received from psychedelic mushrooms by the mycologist Paul Stamets, which are "... always that we are part of an 'ecology of consciousness', that the Earth is in peril, that time is short, and that we're part of a huge, universal bio-system" (Harrison, Straight, Pendell & Stamets, 2007: 138). So there is good reason to explore psychedelics and ecopsychology, if only for the ecologically orientated and apparent interspecies communication that ensues (Krippner & Luke, 2009), or what Doyle (2009: 21) calls the "grokking of Gaia".

Clearly there is also a certain degree of overlap between psychedelic research and ecopsychology: They share common origins in the counter-culture, human potential, and transpersonal psychology and psychotherapy camps. Indeed, psychedelics themselves were very much intrinsic to the genesis of all these movements in the 1950s and 60s, and even had influence on the evolution of ecology and deep ecology movements in the 1970s. Importantly though, the psychedelic cauldron is also the crucible in which we find many core ecopsycholgical themes bubbling up, be they archetypes, animism, shamanism, paganism, green spirituality, transpersonal psychology, or eco-activism. In short, the two fields are deeply entwined, like two old trees that have grown up trunk to trunk. And yet the literature of the fusion between these two areas is somewhat nascent, with the only prior collection of this kind appearing as a special issue of the *Bulletin of the Multidisciplinary Association for Psychedelic Studies* (*MAPS*, 2009), edited by David Jay Brown. Nevertheless, that issue was on *Psychedelics and Ecology* more generally, rather than ecopsychology specifically so this may indeed be the first such collection.

Nevertheless, as with my predecessors editing the last issue of this journal, on *Queering Ecopsychology* (Heckert, Milton & Barker, 2012), it occurred to me that many of the submissions were somewhat thin on psychology per se, and I too wondered if they were "psychological enough". That said, when dealing with psychedelics in the context of ecology it is hard to avoid the interaction between 'mind' and 'nature', which Greenway (2009) reminds us is *the* core relationship of ecopsychology. Because, even if it is not explicit, psychedelics *de facto* imply psychology once you wade in and get your wellies dirty. For psychedelics are nothing if not 'mind manifesting', as indicated by the naming of them as such by Humphry Osmond in 1957. Somewhat more aptly these substances have also recently been dubbed *ecodelics* by Richard Doyle (2011) who suggested that the ecodelic insight arising from the ingestion of these plants and fungi is "the sudden and absolute conviction that the psychonaut is involved in a densely interconnected ecosystem for which contemporary tactics of human identity are insufficient" (p. 20).

So while there is a good dose of psychedelic ecopsychology in this special issue it is as much psychedelic eco-anthropology, eco-ethnobotany, eco-semiotics, ecopharmacography, transpersonal ecology and ecosophy (as Schroll prefers), and even psychedelic ecology. But given that this is the *European Journal of Ecopsychology* I won't even mention the fact that all but one of the contributors reside in the Americas, as this merely suggests we have some catching up to do in this arena on this side of the pond.

The voices of the Earth

Taking the historical perspective, **Rob Dickins** guides us through the early psychedelic and very much psychiatric 'triplit' of the first decade of (what he calls) pharmacography, spanning 1954-1963. In doing so, it is surprising that those early texts he dissects do not have an inherently ecodelic predilection - seemingly due to the laboratorial set and setting favoured at that time - and yet these proto trips paved the way for what was to come with the engendering of an intrinsic interconnectedness between the user and Nature within the psychedelic experience. But this transition was very much a steady evolution, so eventually - after *The Doors of Perception* (1954) and *Heaven and Hell* (1956) - with the book *Island* (1962), we see that "Huxley implicitly recognizes that the natural world is under threat", although unfortunately "any ecological concern in the text is undermined by his pessimism; green awareness fades into the background of a pure white light of mystical experience and his darkly-coloured perception of the social world that threatens it". Yet, despite Huxley's gloom, there remained the interconnectedness that would later form the core of the psychedelic community's coming embrace of trans-speciesism.

Nowhere is this interconnectedness more apparent than with one of the planet's oldest surviving and most culturally intact indigenous psychedelic-plant using people, the Wixáritari (Huichol) of Mexico. A shamanic, animist and pagan people, the Wixáritari have a deeply ingrained relationship with, and reverence for Nature which weaves intimately around their use of the psychoactive peyote cactus, itself synonymous with the deer and the maize, forming their holy trinity of Nature on which they depend. For the Wixáritari, Nature is at the core of their culture: take away the maize, deer or peyote and the culture ceases to exist. Maintaining access to their sacramental cactus since leaving their homeland to avoid the Spanish conquistadors some 500 years ago, the Wixáritari embark, on foot, on a pilgrimage each year some 600 miles (as the crow flies) to collect the peyote from their sacred land. However, their fate as a culture is poised in the balance as Canadian mining interests seek to destroy the habitat in which their peyote grows (Luke, 2012). Exploring this intimate connection with the land **David Lawlor** explores the Wixáritari's unique sense of place, quoting the anthropologist and filmmaker Barbara Myerhoff (1974: 259-60):

> Ecologically, during the peyote hunt the Huichols achieve a spiritual relation to their physical environment - not a neutral setting, not a mere place to live or exploit for a living. The very landscape is sanctified - the caves, springs, mountains, rivers, cactus groves - and the features of the mythical world are elevated to cosmic significance. 'Plants' and 'animals' become only labels, conventions, mere human categories of thought. Distinctions between them are illusory. Man is nature.

As hinted at earlier, it's not much of an ontological leap from the feeling of interconnectedness to the experience of interspecies communication (ISC), in the following case this is brought about through the music of Western Amazonian shamanism. In particular, **Christina Callicot** not only highlights this interconnectedness but emphasises the importance of recognising our interdependence, ignored as it by modern culture or lambasted by critics:

> Anthropology has been long been criticized for its failure to characterize human interdependence with nature in a way that refrains from idealizing or essentializing indigenous peoples, or portraying them as passive objects of environmental determinism. Conversely, modern industrialized culture fails to recognize our interdependence altogether, with drastic results for all species.

Leaving aside for a moment what we are supposed not to do, besides music, what better way is there to actively engage the interspecies conversation than with poetry? Thankfully **Dale Pendell** is on hand with a feisty bird he encounters and his thoughtful dog to remind me that psychedelic ISC need not necessarily mean parapsychologists (like me) labcoating around trying to measure ecodelic ESP:

> ...are we really thinking the same thoughts - are we really in telepathic communication - or is it merely seeming? Perhaps we could devise subtle experiments, with controls. Psychologists without enough to do could write a paper. Or we could continue, and let the continuing be the confirmation.

Using psychedelic plants, or indeed fungi, to join the interspecies conversation also forms part of Graham Harvey's *Animist Manifesto* because "Maybe sometimes the mushrooms just want to help us join in the big conversation that's going on all around us" (Harvey, 2005: 128). There's no denying either, that once you start talking with fungi you are very likely well on the road to the kind of animism we see at play in possibly every shamanic culture utilizing psychoactive flora, fauna (rarely) and fungi[2]. **Robert Tindall**'s story is no exception and he puts forward a fascinating discussion and account of the use of the psychedelically-informed animist worldview to heal human ailments, calling on what shamans call teacher plants, or even doctors:

> Both the medicines and the patient are sung over with icaros, the magical melodies that contain and transmit the healing virtue of the plants. As well, ayahuasca ceremonies are utilized to better enable the *curandero* to direct the spirits of the plants and other 'doctors', and for the patient to more thoroughly integrate the healing received.

Such traditional shamanic practices that utilise psychedelic lifeforms are probably at their most vital and widespread among the prehispanic cultures of Latin America, and yet neo-shamanic practices which incorporate elements of these culturally-bound traditions can be found proliferating across much of the industrialised world. Fifty years since Leary, Metzner and Alpert (1964) published *The Psychedelic Experience* as a guide for fledgling psychonauts at the beginning of the popular era of psychedelics, pioneering ecopsychologist and psychedelic researcher **Ralph Metzner** here explores the activity and utility of these psychedelic neo-shamanic groups for ecopsychological means, particularly within the United States. Informing us that:

> The revival of shamanic ritual practices and an animistic worldview can be seen as part of a worldwide human response to the degradation of ecosystems and the biosphere. These groups and individuals are expressing a new awareness, as well as a revival of ancient awareness of the organic and spiritual interconnectedness of all life on this planet.

Nevertheless, in places like the United States - where there exists no continuous cultural use of psychedelic plants - if neo-shamanic groups intend to make use of such mind-blowing biota then they are likely to encounter the problem of natural local supply. Exploring the 100-mile diet and issues of bioregionalism **Eleanora Molnar** explores the practical ecological challenges of sourcing one's favoured flora, asking if:

> In trying to attain a level of elevated consciousness and understanding, are psychonauts actually acting in ways that are disrespectful of plant spirits, indigenous cultures, and the biosphere in general? Are psychonauts participating in yet another folly of an industrialized, materialistic, and consumer-based culture?

Re-framing the respect required for the negotiation between human mind and Nature at large, and moving from bioregionalism to biogenetic structuralism **Michael Winkelman** presents a co-evolution of psychonauts and psychedelics from our primate antecedents to their current *Homo* descendants. Furthermore, Winkelman looks to the future too to identify that the:

> common features of shamanism, psychedelic metaphysics and ecopsychology illustrate that they involve common origins. Their commonalities point to a biologically based ecopsychology, one that is the product of human evolution and evolutionary adaptations. These biological bases suggest that shamanic ecopsychology and psychedelic therapies still have relevance for humans today. Our very health and survival as a species may depend on our ability to re-establish these relations with nature.

Not only may our health as a species rely on a reconnection with Nature but maybe, as David Orr notes, by healing the planet we heal ourselves, and **Mark Schroll**, taking an autobiographical approach to the issue, indicates that nothing less than a transformation of consciousness is required to solve our current ecocrisis. The catalyst for this conversion, Schroll tells us, resides within Nature's most potent plants, because the:

> psychedelic experience provides us direct access to universal archetypal truths that transcend the boundaries of culture and the limitations of spacetime. Psychedelic experience allows us to encounter visionary mystical insights about the human condition, Gaia consciousness, deep

community and cosmic unity.

Drawing together this overview, if there is an overarching theme here in this special issue, it is that psychedelics - with the right set and setting - can give rise to a sense of deep connection with Nature, which may extend as far as interspecies communication or the formulation and maintenance of an animist worldview, subsequent healing, and ultimately ecocentric activism as opposed to egocentric action. Coming full circle then to my own animistic dialogue with Nature under the influence of a psychedelic plant all those years ago, if there is a metaphor in my own metamorphosis it's that we as a species must change or be changed if we and other species on this planet are to survive. The starting point for that transformation into becoming a part of, rather than apart from, our ecosystem is our own individual consciousness.

Acknowledgements

My thanks to the EJE's founder and editor Paul Stevens for his unstinting support, to the authors, whether published here or not, who submitted papers to this special issue, and to the blind reviewers who contributed such valuable feedback, including Cameron Adams, Kim Dawson, Graham Harvey, Jeremy Narby, Dale Pendell, Tom Pinkson, Alan Piper, Paul Stevens, Nick Totton, Robert Wallis and Michael Winkelman.

Footnotes

1. A psychedelic has been defined as a substance "...which, without causing physical addiction, craving, major physiological disturbances, delirium, disorientation, or amnesia, more or less reliably produces thought, mood, and perceptual changes otherwise rarely experienced except in dreams, contemplative and religious exaltation, flashes of vivid involuntary memory, and acute psychoses" (Grinspoon & Bakalar, 1998: 9).
2. Indeed, "a survey into people's exceptional experiences with psychedelics found that encountering the 'spirit' of the ingested plant or fungus was the most widely reported of a range of 17 'paranormal' and 'transpersonal' type experiences occurring with those taking psilocybin-containing mushrooms (Luke & Kittenis, 2005). According to the respondents this encounter also occurred quite frequently, and was the second most prevalent experience with any one substance, preceded only by experiences of 'unity consciousness' on LSD. Additionally, the encounter with 'plant consciousness' was the most widely reported transpersonal event for several other psychedelic substances too, such as ayahuasca, *Salvia divinorum*, and the *Amanita muscaria* mushroom" (Krippner & Luke, 2009: 13-4). Curiously, the experience of encountering the spirit or intelligence of the ingested substance for synthetic compounds or pure molecules (e.g., LSD or DMT) was much less commonly reported, as might be expected, though the fact it was reported at all throws up some interesting questions (not explored here) about the perceived sentience of plants/fungi versus molecules alone.

Abstract

The use of entheogens tends to particularly thrive in the western regions of North America, in places also characterized by a strong ecological ethos, sometimes expressed as *bioregionalism* (i.e., Vancouver, Portland, San Francisco). Although entheogens and bioregionalism coincide and arguably have some significant things in common, there has been, to date and in practice, very little explicit connection between these two phenomena. More precisely, there is little evidence that users of entheogens are guided or influenced much by bioregional thought, or by related ecological values and frameworks. The academic literature on this topic is virtually non-existent. Nevertheless, there are some relevant ethical considerations regarding the use of plant-based entheogens (including fungi) outside of the geographic areas in which they were grown. This article explores various ways in which this apparent disconnect may be problematic, and discusses possible connections which, if pursued, could foster more responsible use of entheogens from a global and ecological perspective. An overview of bioregionalism and related concepts is offered next. Following that, some of the issues and impacts raised by non-bioregional uses of entheogens are discussed, and the article concludes with some thoughts on approaches to reconciling these problems.

Keywords: entheogens, bioregionalism, ethics, animism, drug tourism.

Introduction

The methodology used to gain knowledge on the variety of psychedelics used, the monetary costs, and the cultural and social milieu in which they are commonly used was ascertained through informal conversations with approximately 50 anonymous people who use psychedelics on the West Coast of North America. Primary locations that data were gathered included Vancouver and Roberts Creek, British Columbia, San Francisco, and Portland, Oregon. The data referred to in this paper were gathered from roughly 2010 to 2013, although the author has been informally researching this area for 25 years, first and foremost in British Columbia.

Overview of bioregionalism and related concepts

A bioregion is an area that can be defined by ecological or geographic boundaries:

> Bioregionalism has a number of characteristics and these include a belief in natural, as opposed to political or administrative, regions as organizing units for human activity; an emphasis on a practical land ethic to be applied at a local and regional scale; and the favoring of locally and regionally diverse cultures as guarantors of environmental adaptation, in opposition to the trend towards global monoculture (Alexander, 1996).

Kirkpatrick Sale (1984), an originator and proponent of bioregionalism, says that we must become "dwellers in the land" and that we must "come to know the earth" in the places in which we live. He quotes E.F. Shumacher to define the quintessence of bioregionalism:

> In the question of how we treat the land, our entire way of life is involved. We must somehow live as close to it as possible, be in touch with its particular soils, it waters, its winds. We must learn its ways, its capacities, its limits. We must make its rhythms our patterns, its laws our guide, its fruits our bounty.

Bioregionalism can perhaps be best described as a philosophy or sensibility. Ralph Metzner (1995) writes:

> The primary values, from a bioregional perspective, are not 'property rights' and 'development' but the preservation of the integrity of the regional ecosystem, the viability of the biotic community, and maximizing economic self-sufficiency within the region.

Although bioregionalism has not crystallized in its full political vision (the redrawing of political boundaries along ecological or bioregional lines), it remains a persistent alternative undercurrent, an important component of the broader environmental movement. Indeed, it can be argued that bioregionalism's focus on all things local and regional anticipated or at least exerted an important influence on debates that eventually unfolded more in the mainstream - in particular, free trade, globalization, local foods and ecological footprint. And in many ways the roots of bioregionalism, in eco-philosophical terms, extend deeper than those of other environmental frameworks. For these reasons, it is argued that bioregionalism provides an important framework within which to consider the ecological, social, cultural and spiritual dimensions of entheogen use, embedded in place or elsewhere.

Furthermore, Metzner clearly states the parallels between bioregionalism and entheogens. In *Green Psychology*, he makes the assertion that the renewed ceremonial and ritual uses of entheogenic plants are a symptom of an emerging grassroots paradigm shift towards more holistic thinking in terms of ecological issues and values. He states:

> I would argue that at a time when global techno-industrial culture is leading to massive erosion of biodiversity, worldwide ecosystem destruction, and profound social and economic disintegration, there are a number of cultural movements that are cautiously and purposefully moving toward the articulation of an ecological worldview and a bioregional, sustainable lifestyle. Among movements with similar values and assumptions I would include the revival of interest in herbal, homeopathic, and natural medicine; shamanic practices; bioregionalism; deep ecology; ecofeminism; social ecology; environmental ethics; ecopsychology; ecotheology; green economics; and the neopagan revival (Metzner, 1999: 8).

While Metzner makes the explicit connection between sustainability, bioregionalism, and enthoegenic use, he seems to view them as mutually supporting practices. This paper makes the observation that current use of entheogens among psychonauts and seekers on the West Coast of North America is not always so and sometimes rather to the contrary.

Ecological footprint and the 100 mile diet

Environmentalism and, more particularly, bioregionalism, are umbrella terms that cover many related concepts and initiatives, two of which are ecological footprint and the 100 Mile Diet. Mathis Wackernagel and William Rees conceived the notion of an ecological footprint, defining it as:

> The total area of land required to sustain an urban region (its 'Ecological Footprint') is typically at least an order of magnitude greater than that contained within municipal boundaries or the associated built-up area. In effect, through trade and natural flow of ecological goods and services, all urban regions appropriate the carrying capacity of distant 'elsewheres', creating dependencies that may not be ecologically or geopolitically stable or secure. ... Such macroecological realities are often invisible to conventional economic analysis yet have serious implications for world development and sustainability in an era of rapid urbanizations and increasing ecological uncertainty (Rees, 1992: 121).

More simply stated, the Ecological Footprint is a measure of the impact put on land and water in a very particular region by its population. Essentially this measurement is a means to help people and societies delve into notions of sustainability and develop the understanding that we must live within nature's limits and carrying capacity (Wackernagel & Rees, 1996).

Perhaps inspired to some extent by the concept of an Ecological Footprint, the 100 Mile Diet was conceptualized in order to increase food security and to reduce social, environmental, and economic costs associated with importing and consuming foods that cannot be locally grown in a particular region or season. Smith and MacKinnon (2007) established a 100-mile radius from their residence in which they were to source their food for one year (2005-2006) and this is an example of bioregionalism applied to food systems. Some Diet benefits include reducing one's carbon footprint, eating healthier by reducing intake of processed food, weight loss, awareness of food systems, stimulating the local economy, and creating jobs. Some Diet challenges include learning how to preserve local food in season, changing eating habits, and potentially adopting a plant-based diet in some locations where meat and dairy items are not produced.

Depending on the context, food-based movements such as the 100 Mile Diet (exemplary of bioregionalism) and environmental concepts such as the Environmental Footprint may be quite distinct or strongly interconnected, but in most instances they are highly complementary. For example, the concept of bioregionalism is being applied to all kinds of consumer activities and "buy local" campaigns are ubiquitous whether applied to locally sourced building materials, food, tourism, entertainment, and clothing.

Although it appears that the concepts of bioregionalism and the Ecological Footprint have been accepted most wholeheartedly in the sphere of food security, these concepts have not been equally accepted by psychonauts (entheogen users who seek self-knowledge). This is because many psychonauts are not often consuming entheogens grown in their bioregion and are inadvertently expanding their Environmental Footprint. Paradoxically, this is not reminiscent of the 100 Mile Diet nor the associated concepts of bioregionalism and sustainability that Metzner couples with entheogenic consumption and shamanic practices. As an aside, it is worthy of note that the 100 Mile Diet is not necessarily concerned with the spiritual implications of food while this is a relevant consideration that pertains to entheogens. This consideration will be discussed later in this article.

Issues, impacts and consequences of non-bioregional use of entheogens

Contemporary uses of plant-based non-indigenous entheogens leave sizeable footprints that involve ecological, social, cultural, and spiritual considerations that may contradict the intentions of psychonauts and the paradigm of moving towards more sustainable communities. Some key considerations involve the inordinate amount of resources used in transportation, cultural appropriation, the commodification of plant medicines and altered states of consciousness, overharvesting and the possible displacement of traditional plants and their spirits. It is argued that at least some of these undesirable impacts and consequences could be avoided or minimized if users ingested only locally grown plant-based entheogens, plant-based analogues or synthetic versions of plants that are not available locally. The extent to which psychonauts are aware of the implications of their use is unclear, as there is very little discussion of this topic in the entheogenic discourse.

It can be generally observed that here is a recent surge of entheogenic ceremonies in North America, in particular with considerable activity in the western coastal regions. In many instances, sacred indigenous plant-based entheogens, primarily ayahuasca (and also including iboga, peyote and psilocybin), are imported from distant geographic locations to serve the needs of those seeking cognitive enhancement and spiritual (healing) experiences. The frequency and high participation rates of non-psychonauts in these kinds of ceremonies are a relatively new phenomena, as are the ceremonies themselves. It is possible that these neotraditional ceremonies have been taking place for some time yet it appears that these once lesser known practices have entered the cultural mainstream and the number of ceremonies and people partaking in them have increased significantly (personal communications with 50 anonymous interviewees). Information about ayahuasca ceremonies is ever-present in the mainstream media and climate as evidenced by an article in *Vanity Fair* in 2011 entitled "Letters from the Amazon" by Ted Mann. The article makes reference to an ayahuasca ceremony in a northern Los Angeles house, to ceremonies in the Amazon, and to the author's personal experience in a ceremony. The article certainly delves into the realms of ayahuasca culture and tourism, giving the sense that these experiences are commonly shared amongst everyday people, as opposed to the rather select realm of psychonauts.

Based on the author's anecdotal understanding of these ceremonies, and particularly those in British Columbia, they include the use of ayahuasca, iboga, peyote and psilocybin (personal communications with 50 anonymous interviewees). Some of the neo-traditional ceremonies involving peyote and ayahuasca are structured on traditional indigenous practices (i.e., the Native American Church) and others have been adapted to the sets and settings of North American culture (cross-cultural Vegetalismo) (Tupper, 2009). These ceremonies are referred to as neo-traditional because they are being held outside of their traditional geographic boundaries and are often presided over by neo-shamans (Tupper, 2009).

Psychonauts and seekers alike are to a great extent ingesting entheogens from a global market, rather than ingesting locally grown plant-based entheogens. For example, it is now possible to procure ayahuasca from Peru, peyote from Mexico, and psilocybin mushrooms from Canada all in the same day. While ingesting these psychoactive plants (and fungi) all at once is not likely or advisable, it is possible, and raises some questions about the local use of non-indigenous entheogens. This conundrum is common but is almost ironic in the sphere of entheogen use. Ostensibly, one result of ingesting entheogens in a ceremonial or therapeutic context is that people may ultimately be more aware of the interconnectivity and the sacredness of life, sometimes referred to the internal and external reality of mystical experience (Griffiths, Richards, McCann & Jesse, 2006). As a result of this awareness, psychonauts may try to lead more balanced lives that have fewer negative impacts on others and the planet. "The worldview of shamanism is that health equals balanced relationships with all living things" (Gray, 1995: 173). Yet the considerations of Ecological Footprint so far appear to be rarely, if ever, applied to the use of entheogens in neo shamanic and neo traditional practices.

One of the most obvious impacts is the inordinate amount of resources used in harvesting and transporting entheogens. Our globalized transportation systems require various inputs such as fuel, labour, and vehicles and the result is often a large Ecological Footprint. While these transportation systems are already in place to serve other means, it does not diminish the amount of total resources used to transport entheogens globally. Also implicit in the discussion of imported plant resources is the problem of overharvesting. Some ethnobotanists assert that the answer to overharvesting in indigenous habitats is the propagation of non-indigenous plant-based entheogens in native habitats; yet this scenario can also be problematic. Although propagation may appear to be a more benign scenario, there is the risk that foreign plants may become invasive when introduced into native landscapes. In many instances, long-term time frames are needed to assess how well introduced species are adapting to native habitats. Conversely, others might advocate for non-native plants to be grown in controlled environments to lessen the chance of proliferation or accidental cross pollination. However, if entheogens are being grown in controlled and artificial environments such as greenhouses or in cultured tissue, they require large amounts of resources for successful propagation and harvest; inputs may outweigh outputs and Ecological Footprints are being expanded.

Another justification for cultivation and use of plant based entheogens in nonindigenous habitats is that humans are indeed part of nature and like animals are spreading the spores and seeds of entheogenic plants globally. This assertion does hold some possibility if it were not for the fact that animals tend to habituate in certain bioregion(s) (based on seasonal migrations and other natural processes). Unlike humans, animals do not have a global habitat. Due to modern advancements in transportation networks, one can travel the globe and create multiple waste streams while attaining a seemingly vital worldly education. It is arguable that if one needs to consume a plant-based entheogen that cannot be sourced locally, a synthetic version or indigenous plant-based analogue might present a more ecologically sound alternative.

Some have asserted that plant-based entheogens such as ayahuasca "want" to be spread all over the earth to multiply their reach and "wake up" earth's inhabitants to the message of honoring her, each other, and ultimately the unity consciousness woven between us (McKenna, 2005). In response to this message, ayahuasca is being bred in non-indigenous places such as Hawaii and Costa Rica. Not only is this being done to spread the spiritual message of the plants, it is also being done to save the dwindling plant resources in their indigenous locales (partially as a result of increasing drug tourism).

In addition to the ecological issues raised previously, there are a number of social and cultural implications to ingesting non-indigenous plant based entheogens, such as ayahuasca. Stresses such as drug tourism and the global marketing of plant-based entheogens are putting considerable strain on indigenous communities. (Dobkin de Rios, 2009). In her 2008 book with Roger Rumrill, Marlene Dobkin de Rios discusses the issue of drug tourism:

> [Drug Tourism] has been around for more than 40 years and has been getting worse each year. Westerners take tours throughout areas of the Amazon and experience 'borrowed mysticism'. The drink ayahuasca is given to them by new, often false shamans - so called 'technicians of ecstasy' - charlatans who are on the lookout to profit from altering their clients' consciousness (p. 2).

They elaborate that drug tourism is taking place as a result of social alienation and Western cultural norms:

> …the urban tourist is on a never-ending search for self-actualization and growth. In this postmoderm period where people no longer produce their own food, where the family has broken down, where there is a significant absence of community tradition and shared meanings, individuals are wracked with feelings of low self-esteem and confusion about values. They are compelled to fill the emptiness with the experience of receiving something from the world. Why not a mystical experience with divinity (pp. 69-70) ?

They further go on to quantify the monetary exchange that vastly differs in value between the West and in the traditional cultures of the Amazon:

> Modernization and cultural change over the last century have destroyed the material base of many Amazonian traditional cultures. Commercial shamanism in Peru has become a system, where foreigners are given a powerful plant psychedelic at a cost of $1,000-$1,500 per week during a visit, compared to the $20-$30 cost for local people (p. 71).

Drug tourism is a global phenomenon, particularly in the Amazon Basin where tourists are looking for a "genuine" ayahuasca experience. While Dobkin de Rios primarily speaks of ayahuasca, she clearly illustrates some of the impacts of drug tourism that include con "neo shaman" and the exorbitant commoditization of culturally sacred ceremonies.

Cultural appropriation is implicit in the discussion regarding drug tourism and bioregionalism; this is yet another consideration. Cultural appropriation "assumes the existence of power differentials between the source culture and the privileged authoritative position of the borrower culture" (Tupper, 2009: 123). It could be argued, for example, that neo-traditional ayahuasca, iboga, peyote, and psilocybin ceremonies practiced in British Columbia are forms of cultural appropriation. These ceremonies are sacred in indigenous cultures and arguably cannot be easily transferred to North American culture with the same reverence and meaning by neotraditional shamans and psychonauts. Tupper (2009) speaks to the ways that cultural appropriation can manifest itself:

> (cultural appropriation) undermines the integrity of the community whose culture is

> appropriated; and it has an impact on the cultural object itself (for example profanation of a sacred practice). It also permits inappropriate distribution of material rewards (namely financial gain) to the individuals doing the appropriating; and it fails to acknowledge the legal sovereignty over a kind of intellectual property (p. 124).

While this article cannot do justice to the ways in which drug tourism and cultural appropriation is taking place in neo-traditional ceremonies, ingesting locally harvested or synthesized entheogens that do not require the guidance of a shaman or the sacred ritual of a traditional indigenous ceremony may avoid issues of cultural appropriation (and drug tourism).

Animism and animaphany

With respect to the cultural and spiritual considerations regarding non-indigenous plant entheogens, one could pose the question: "What do the plants themselves have to say?". While this may seem a ridiculous question to some, it may be a tangible area of inquiry to those who have taken entheogens, those who revel in nature, and those who believe in animism.

J.E. Lovelock wrote *Gaia: A new look at life on Earth* in 1979 and suggested that perhaps the Earth has agency. He speaks of this hypothesis, "in which Earth's living matter, air, oceans, and land surfaces form a complex system which can be seen as a single organism and which has the capacity to keep our planet a fit place for life" (p. x). Lovelock follows up by stating "occasionally it has been difficult, without excessive circumlocution, to avoid talking of Gaia as if she were known to be sentient" (p. xii).

Furthermore, Lovelock also speaks of the inherent knowledge contained within Gaia that is ineffable:

> Among several difficult concepts embodied in the Gaia hypothesis is that of intelligence. Like life itself, we can at present only categorize and cannot completely define it. Intelligence is a property of living systems and is concerned with the ability to answer questions correctly. We might add, especially questions about those responses to the environment, which affect the system's survival, and the survival of the association of systems to which it belongs (p. 146).

Andy Letcher, likely influenced by Lovelock, calls meetings with the spirits or souls inherent in entheogens - magic mushrooms in particular - "animaphany" (2007: 87). This kind of animistic thinking fundamentally challenges the cultural ontology of experience. The animistic discourse contends that all natural objects, such as plants and stones, have spirits or essences that exist outside of our ordinary awareness. Letcher states that to some people psilocybin mushrooms "facilitate the perception that of plants as being in some sense conscious, aware, and inspirited" (2007: 90). What is it that happens to these spirits when they are transported and consumed outside of the geographical areas in which they originated?

What can be said about the displacement of plant spirits and could there indeed be such a thing? In the shamanistic tradition and animistic discourse, it is not the shamans that do the healing, it is the spirits of the plants (Letcher, 2007). Could it be that entheogenic plants used outside of their indigenous habitat are displaced? Would this change their effectiveness or fundamental structure? Does the physical travel that they endure affect their healing potential?

To add some context to these questions, it might be useful to refer to the unrest of souls or spirits whose previous physical bodies are kept in places that are geographically unfamiliar or were disposed of in ways that are disrespectful. The repatriation of ancestral remains by indigenous peoples, such as the Haida, is one such example. One of the reasons for the repatriation of ancestral remains is that by doing so, displaced spirits can finally be at rest.

> The main goal... is to bring home and rebury our ancestors with honour and respect. As long as the remains of our ancestors are stored in museums and other unnatural locations, we believe that the souls of these people are wandering and unhappy. Once they are returned to their homeland of Haida Gwaii, and laid to rest with respect and honour, their spirits can rest, and our communities heal a bit more (Collison & Collison, 2002: 8).

Does this kind of spiritual displacement also occur when entheogenic plants and fungi are consumed in geographic areas in which they are not grown? While these questions can not be decisively answered, they are examples of deliberations about the spiritual considerations of ingesting entheogenic plants outside of the geographic locations in which they were grown and in which traditional and neotraditional ceremonies take place.

Concluding thoughts

Clearly, traditional entheogenic uses and practices are evolving into new forms. A recently published paper argues that the International Narcotics Control Board may criminalize "legitimate cultural practices outside their alleged 'original socioeconomic context'" (Tupper & Labate, 2012). To be clear, the present critique of contemporary uses of plant-based entheogens in no way suggests that only bioregional approaches to entheogenic uses should be legal. Rather, it merely argues that perhaps there are less ecological, social, cultural, and spiritual impacts when only indigenous plant-based entheogens are ingested.

We live in a time of continual fast-paced change and development devoid of shared values, including the worth of self-knowledge. As a result, people are dislocated and are feeling as though they need a respite from the bombardment of industrial values such as materialism and consumerism (Alexander, 2000). It may be that the proliferation and popularization of neo-traditional ceremonies is a response to the spiritual and cultural longing for shared values, self-knowledge, and a sense of unity in the times that we live in (Dobkin de Rios & Rumrill, 2008). In trying to attain a level of elevated consciousness and understanding, are psychonauts actually acting in ways that are disrespectful of plant spirits, indigenous cultures, and the biosphere in general? Are psychonauts participating in yet another folly of an industrialized, materialistic, and consumer-based culture?

The question "Is it ethically responsible to use only locally grown plant-based entheogens?" is not a simple one. It may be possible that the ingestion of entheogenic plants, outside of their geographic areas of origin, are both dishonoring and nurturing to the planet and to Western culture at the same time (through the impacts outlined in this paper and through the benefits of experiencing self-knowledge and unity consciousness inherent in most entheogenic experiences respectively). Furthermore, in the future a bifurcation point could make it more apparent as to what the "ethical" path is. While this assertion may be simplistic, it acknowledges the unknown, especially with respect to the spiritual dimensions of bioregionalism. With this acknowledgement it is sensible to adopt a precautionary principle approach because we inhabit a fragile interconnected web of life and need to consider the long-term consequences of transporting, propagating, and consuming sacred plants and fungi from around the world.

Even though the concept of eating locally is well supported by many, it is acted on by too few. Comparatively, only a small fraction of the population chooses to explore non-ordinary states of consciousness and the deliberation regarding entheogens and bioregionalism may seem peculiar. Nevertheless, this consideration will be timelier as psychonauts' forays into cognitive enhancement become a more accepted and diverse practice, both for therapeutic and medical uses (Fadimann, 2011; Roberts & Hruby, 2002).

A bioregional approach to using entheogens provides a way to address the issues raised in this paper and it is worthy of note that psilocybin mushrooms grow in almost all parts of the world. Does this fact suggest a message the plant (fungi) spirits may be trying to convey? It is indeed if one seriously considers the truth of animaphany and the assertions made about the earth having its own agency (Letcher, 2007; Lovelock, 1979; McKenna, 2005).

In conclusion, this article has sought to explore the ethical way forward with respect to ingesting local plant-based entheogens or synthetic analogues given the potential impacts previously discussed. Perhaps a further deliberation of what is ethical requires more listening to what the plant spirits are trying to teach us (and how we can learn from respectful dialogue with one another):

> ...it is surely safe to say that the path of sanity, perhaps survival, is to regain the spirit of the ancient Greeks, to once again comprehend the earth as a living creature... we must listen again to the two great teachers, one 'the marvelous system of living nature' and the other 'the traditional

> wisdom of mankind', teachers we have 'rejected and replaced by some extraordinary structure we call objective science'... (Sale, 1984).

Abstract

This paper is an autobiographical overview of the variety of influences that continue to foster my ongoing transition from ecopsychology to transpersonal ecosophy. These influences (both personal and professional) are discussed throughout this paper; and include transpersonal psychology, shamanism, and psychedelics. This chronicle of influences and associated events serves to reclaim ecopsychology's history. In addition, a brief examination of the eco-dissociated limitations within Hinduism, Taoism, and Buddhism are discussed as a reminder of the fragmentation of theory and practice within traditions that are otherwise considered to be pathways to enlightenment.

Keywords: transpersonal, ecosophy.

Prologue

On March 27, 2004, I chaired a symposium I organized on "Psychedelics: Their value and social responsibility" for the spring conference of the Society for the Anthropology of Consciousness, held at the University of California-Berkeley, Berkeley, California (UC-Berkeley). Participants included Ralph Metzner, Adele Getty, Stanley Krippner, Maura T. Lucas, and among the audience members was Mary Gomes. Gomes (along with Theodore Roszak and Allen Kanner) served as editor of *Ecopsychology: Restoring the Earth, healing the mind* (1995), yet her interest in my symposium stemmed from the fact Getty and Lucas were among the authors in a 2003 issue of ReVision that Gomes edited on "Women and Entheogens". Telling us, "It seems to me that a shadow of psychedelic exploration, at least as it has unfolded in the West, is a fascination with strange and abstract experiences that expand the mind but fail to open the heart" (Gomes, 2003: 2). Getty (formerly married to Francis Huxley) agreed with Gomes, saying:

> ...over the years there have been large conferences that address in great detail various aspects of psychedelics ... . most of the speakers are what I call 'Molecule Men' ... They can rattle off long chemical alphabets and even longer polysyllabic terminology explaining neurotransmitters, MAO inhibitors, [etc.] ... Considering the times we live in, this is a wonderful accomplishment, and these scientists should be congratulated and supported. ... [But] the healing aspect of psychedelics is ancient and traces its roots back through our genetic memories, into indigenous tribal cultures, around the fire with the drum, rattle, and song of the shaman ... Shhh! Women have [been] burned at the stake for much less (Getty, 2003: 14-7).

In my online correspondence with Robert Greenway (from 2000 to 2010 - which was focused on history and theory), I learned it was Ilan Shapiro (a graduate student of Greenway) who, in 1989, formed a peace studies group at UC-Berkeley in protest of the first Gulf War. This group attracted Gomes, Greenway, Kanner, and eventually Roszak as participants. Among the insights that emerged from this group was that the conflict of war always produces widespread environmental destruction. In this way, "peace studies" and anti-war groups (which are always politically motivated) are directly connected to the conversation and interests that led Roszak to write his 1992 book, *The Voice of the Earth*.

Introduction

> Krippner has pointed out 'It is therefore time for transpersonal psychology, and transpersonal studies in general, to reassess and reclaim its history regarding ecopsychology so it can step forward and fill this void. I have to say that the psychedelic movement caught on to this long ago. I remember back in the 1960s, when people began doing informal work with psychedelics. One theme that came up time and time again was we are destroying the environment, and that taking psychedelics increased not only our appreciation of nature, but all forms of life. I think too the psychedelic movement has been given short shrift by historians in a number of other ways, because it also helped stimulate interest in the Peace Movement, the Civil Rights movement, et cetera (Schroll, *et al*, 2009: 47)[1].'

Krippner's comments support my decision to write an overview and autobiographical reflection on my involvement in ecopsychology's historical development, and how the ecopsychological perspective dovetails with studies of shamanism[2], psychedelics[3], transpersonal psychology[4], and the emergence of *transpersonal ecosophy*. My knowledge and understanding of transpersonal ecosophy emerged from a symposium I organized on "The History and Future of Ecopsychology" for the Society for the Anthropology of Consciousness 2009 conference on "Bridging Nature and Human Nature". It was during this symposium Alan Drengson pointed out, in response to Warwick Fox's *Toward a Transpersonal Ecology* (1990), that Arne Naess said a better title would have been "Toward a Transpersonal Ecosophy" (Schroll, 2011c: 4). Shortly after this conference Drengson sent me a copy of his book *The Ecology of Wisdom: Writings by Arne Naess* (2008), edited with Bill Devall, which reiterated this point:

> Warwick Fox suggests that those, including Naess, whose ultimate premises call for an extended sense of identification with an ecological self be called transpersonal ecologists, but Naess would say that they have transpersonal ecosophies (p. 37).

> Ecosophies are not platforms for a political movement or policies [Drengson and Devall explain] but are personal philosophies of life in a worldview (p. 33).

Ecosophies therefore serve the same function as personal myths or our personal mythology, defined as "more than just intellectual constructs; they are ingrained models of reality that determine how you see your world and understand your place within it" (Feinstein & Krippner, 1988: 2). Moreover the term transpersonal ecosophy fosters an interdisciplinary perspective more so than the term ecopsychology, as well as helping to free us from the criticism put forth by Susan Clayton and Gene Myers:

> The relationship between ecopsychology and psychology however, is contested. Not all ecopsychologists are trained as psychologists, and writings on ecopsychology have been criticized for a lack of scientific objectivity, referencing concepts like spirituality and indigenous wisdom that are difficult to clearly define. Reser in a thoughtful critique [(1995)] concluded that the assumptions and methods of ecopsychology are too disparate from accepted psychological standards to be considered an area within psychology (Clayton & Myers, 2009: 10).

First, Clayton, Myers, and Reser are incorrect that spirituality is difficult to define - see Elkins *et al*. (1988) and Lazar (2009) for definitions of spirituality. Whereas the difficulty associated with spirituality, according to my discussions with John Rowan, is not our inability to define it:

> It is because of the various meanings and [often conflicting] uses of the term spirituality that I [Rowan] prefer to use the term transpersonal. ... The main advantage of using the term transpersonal is ... [it places or refers us to states of awareness that follow] after the prepersonal and the personal in the process of psychospiritual development. ... Not so with spirituality, which roams all over the place (Schroll, Rowan & Robinson, 2011: 124-5).

Second, Jurgen W. Kremer has given precise definitions of "indigenous wisdom" or "indigenous science" in an issue of the journal *ReVision* (1997). See also Pamela Colorado's (1996) paper, "Indigenous Science". Third, confining ecopsychology to standards within psychology limits it to something that Roszak and Metzner agreed it was never intended to be (Metzner, 1993, 1999: 2). Roszak argued, "Saving the life of the planet is the biggest political cause humans have yet taken on; it requires a vision of the human personality that is just as big" (Metzner, 1999: x).

All this harks back to Krippner's observation about informal assessments with psychedelics in the 1960s, and supports the view, "that taking psychedelics increased not only our appreciation of nature, but all forms of life". This is supported by a frequently quoted passage from Albert Hofmann's book *LSD: My Problem Child* (1983: ix-x), recalling a peak-experience in nature at age nine, that provided him with the ability to recognize his accidental ingestion of LSD, in April 1943, was of similar psycho-spiritual origin. Metzner adds the observation that LSD's discovery "in 1943 at the height of WWII occurred within months of Enrico Fermi's first controlled nuclear chain reaction, which led directly to the building of the atomic bomb; as if it was a kind of psycho-spiritual antidote to the death weapon" (2008: 21). Unfortunately the wealth of knowledge that could help us support these claims about the connection between psychedelics and ecology came to an end in 1965, "when the government clamp-down occurred, [and] even clinical research was banned" (Smith *et al*, 2004: 123). Some recent exceptions have been made, such as MacLean, Johnson & Griffiths (2011), the significance of which we shall discuss later in this paper. Still, for most of us, the ban on any experimentation with psychedelics continues. Thus, on the one hand, this "makes the surviving early researchers a uniquely valuable group," and "because of their advancing age are clearly an endangered resource" (Smith *et al*, 2004: 123). On the other hand, the near total ban on psychedelic research eliminates most of us from replicating its influence on our relationship with nature and other species - with the exception of anthropologists of consciousness who investigate indigenous cultures (Beyer, 2009, 2012; Dickens & Tindall, 2013; Harrison, 2011; Webb, 2013).

Among these endangered resources is Stanislav Grof (a pioneer in psychedelic research and transpersonal psychology), who said, in response to the question, "Can you describe the circumstances and impact of your first psychedelic experience":

> I began to realize that, even after a long time, the results [of psychoanalysis] were not exactly breathtaking. My own analysis lasted seven years, and I loved every minute of it: playing with my dreams, and finding that there was some deep meaning in every slip of my tongue. But if you had asked, "Did it change you?" I would have hesitated. I would say that, while I changed during those seven years, there was no convincing causal relationship between the free-associating that I did on the couch and the changes that happened in my life. Whereas, *when I had my first LSD session, I was one kind of person in the morning and a whole different kind of person in the evening, and there was no question that this change was the result of the experience* (Grof *et al*, 2008: 156, italics added).

This raises the question, what kind of person did he become? Grof adds:

> Ultimately, we don't have a fixed identity. ... You can eventually experientially reach the cosmic creative Source and become that Source. When you have that experience [like I have,] you realize that this Source is no different from the overall field of cosmic energy" (Grof *et al*, 2008: 167)
>
> [Consequently] It becomes obvious that the universe is a unified web, of which we are all meaningful parts ... . [and,] that we are facing a problem of a collective nature that only a determined cooperative effort can solve. ... [Thus] a radical and lasting solution is inconceivable without inner transformation and a move toward global awareness (Grof, 1985: 39).

Therefore in an attempt to put all of these concerns into their proper perspective, this paper will proceed chronologically from past to future (and periodically flash forward and backward in time so that particular points can be addressed). Equally important for us to know before we enter the main body of this paper is portions of it have been published elsewhere, which also raises the question why is there a need to repeat this discussion again? The answer is that I have learned from the past mistakes of Naess and Roszak. Neither of them repeated themselves enough, nor referred back to their early work enough, nor clarified their basic concepts enough, nor explained well enough what it was that motivated them to pursue their respective areas of research. Consequently the task of creating a coherent statement summing up their respective contributions has been left to others. A summing up of Naess' legacy can be found in Drengson, 2005; Drengson and Devall, 2008, and Drengson, Devall, and Schroll, 2011; whereas a summing up from ecopsychology to transpersonal ecosophy is this paper's focus, and listening to the music of the lyrics quoted in this paper will deepen the readers experience.

Recognizing an internal pollution crisis in humankind

Mama nature said, it's murder what you've done,
I sent you forth my brightest world, now it's nearly gone.
Virgin bees been telling me, you can't see the forest for the trees,
Cover up your eyes with sympathies.
And I've got no solution, to your persecution,
I'm so disillusioned.

Mama nature said, you're guilty of this crime
Now it's not just a matter of fact, but a matter of time.
Cruel will be the vengeance, some say I don't believe that story,
And I've got no solutions to your own pollution.
- Phil Lynott/Thin Lizzy, 1973, Belfast, Ireland

> As a teenager growing up in the 1970s, instead of listening to disco, I was contemplating the rock lyrics of songs such as *Mama Nature Said*. Likewise, this zeitgeist was shaped by a cultural background of films such as Soylent Green (1973), (based on Harry Harrison's 1967 book *Make Room! Make Room!*) vividly warning us about the forthcoming dangers of overpopulation, pollution, and food shortages, with ominous overtones of fear, guilt, and self-sacrifice as the only solutions to an otherwise impending apocalypse. At best there were TV commercials featuring Hollywood's version of indigenous tribal elders shedding a tear as garbage was thrown from cars desecrating the landscape, which concluded with a message pleading with us not to litter. But the idea of some kind of "internal pollution" contributing to the ecocrisis was absent in the environmental rhetoric that I was hearing from the adults shaping my adolescent development (Schroll, 2009: 29).

My search to understand this "internal pollution" is what led me to "ecopsychology" (which I suggested in the introduction can be more accurately described as "transpersonal ecosophy"; I will, however, continue to refer to both ecopsychology and transpersonal ecosophy throughout this paper). It was therefore an immediate flash to my memories of *Mama Nature Said* as I heard Ian Prattis tell us in *Failsafe: Saving the Earth From Ourselves* (2008): "I must be blunt from the outset about the context of [our] current ecological, social, and psychological crisis. There is an external environmental pollution crisis on the planet because there is an internal pollution crisis in humankind" (p. 38). Prattis identifies this internal pollution as symptoms (p. 27), which agrees with (yet fails to cite) the work of Roger Walsh who pointed this out in his 1984a article "World at Risk" (pp. 10-14), and elaborated on this point in Walsh, (1984b, 1985). This is an important point that Prattis and Walsh raise, and provides us with the starting point of transpersonal ecosophy: "how, and in what directions, can we move beyond simply treating the symptoms of the world's growing number of social and environmental crises?" (Schroll, 2007: 30). Pondering this question represented a real turning point in my thinking:

> It allowed me to realize that healing the world's social and environmental crises was not going to come about simply by creating new technologies and discontinuing the use of fossil fuels, nor by rejecting the development of new technologies and trying to live more simply. It is not a matter of philosophers envisioning a better environmental ethic to guide the practice of conservation biologists and urban planners, allowing us to serve as better stewards of the land. Nor would a concentrated effort of protest by eco-activists employing guilt, fear, and letter writing campaigns, urging politicians to enact stiffer environmental laws, create the kinds of changes needed in our behavior. Necessary as all these approaches might be, I believe that the real starting point toward healing the social and environmental crisis begins with self-confrontation and self-examination. We need to examine the worldview influencing our attitudes and our behavior (p. 30).

Some mainstream environmentalists may take offense with this turning point in my thinking, believing that I no longer support the work of environmental activists, or those involved in resource management, conservation biology, environmental psychology and conservation psychology. But this is not correct. I continue to support these concerns[5], yet I stand in opposition to technocracy, that is, the social engineering of culture. Indeed it was the insights that Roszak gleaned from Mary Shelley's *Frankenstein* (1816/1983) with its critique of science and culture (Roszak, 1980), that motivated him to write *The Making of a Counter Culture: Reflections on the Technocratic Society and its Youthful Opposition* (1969). This particular point was overlooked in both Jonathan Coope's (2010), and Tristan L. Snell, *et al*'s (2011) assessment of Roszak's contribution to ecopsychology. A preliminary effort to address this concern was attempted by Schroll and Greenwood, 2011, yet a more comprehensive inquiry is still needed. Non-fiction critiques of transforming scientific knowledge into technologized social policy include Batteau, 2010; Drengson, 1995, 2011; Fromm, 1968, Glendinning, 1994; and Roszak, 1973, 1999, and are echoed in several fictional critiques (Huxley, 1932/1969; Orwell, 1949; and Zamyatin, 1972). Revisiting these concerns 30 years later, Roszak wrote:

> Cultures keep secrets; they illuminate some things and suppress others. Every culture conceals as much as it reveals; that is its style and its distinctive contribution. Cultures survive as long as they can maintain that style, which means as long as they can hide from themselves. There is a sense in which every culture is a conspiracy, a coordinated effort to open a few doors of perception and to close others (Metzner, 1999: viii).

The difficult problem we face is this, freeing ourselves from the "technocratic paradigm's" grip (Roszak, 1969; Drengson, 2011) will not be easy, because our path to liberation cannot be achieved solely on the basis of logical arguments built on incremental bits of data. Roszak agrees:

> Ecology already hovers on the threshold of heresy. Will it be brave enough to step across and, in so doing, revolutionize the sciences as a whole? If that step is to be taken, it will not be a matter of further research, but a transformed consciousness (Roszak, 1973: 371).

Asking himself similar questions, former Apollo astronaut and founder of the Noetic Institute Edgar D. Mitchell concluded that what we need to solve the ecocrisis "is a transformation of consciousness" (Roberts, 2011: 6). In other words we need a positive vision of the future based on a cultural (anthropological) and personal (existential) understanding of what it means to be human. Only the most skeptical continue to deny that we are now in the midst of the ecocrisis that Rachel Carson (1962) predicted nearly 50 years ago. Skeptics and believers arguing for and against the reality of the ecocrisis have nevertheless missed a more essential point - Carson warned against relying on a "technological fix" as a solution to the ecocrisis, yet this does not mean that technological innovation is not important; it is. I am right now using several kinds of innovative technologies in the completion of this paper, and rely on others in my daily life. What Carson meant was that by itself new technologies will not be enough to solve the ecocrisis, and these solutions are frequently thwarted by technocracy.

Likewise (as I have previously discussed in greater detail):

> in conversations I have had with ecopsychologists who support the hypothesis that a transformation of consciousness is needed, many have asked if it will take some serious apocalyptic environmental catastrophe to motivate most of us (Schroll & Hartelius, 2011: 84).

Ram Dass raised this same concern in his interview with John Seed (Ram Dass & Seed, 1991). Ram Dass asked: "Will it take incredible trauma to trigger a transformation of consciousness?" To which Seed replied (paraphrasing): "We have already had so much trauma this does not seem to be a sufficient means to trigger a change in our awareness. In fact trauma often has the opposite nullifying influence on us"[6]. Instead Seed suggested that what we needed was some sort of miracle that would allow us to "wake up one day different" (Schroll & Hartelius, 2011: 84).

Harking back to Hofmann's anecdotal recollection of the similarities between his experience in nature, and initial psychedelic experience, this raises the question, could ingesting a psychedelic plant such as psilocybin mushrooms influence personality traits and ultimately trigger a transformation of consciousness? Recent experimental evidence in a clinical setting (MacLean, Johnson & Griffiths, 2011) provided data to establish that increased openness did result from subjects ingesting psilocybin. They define openness as "a relatively broad range of intercorrelated traits covering aesthetic appreciation and sensitivity, fantasy and imagination, awareness of feelings in self and others, and intellectual engagement. People with high levels of Openness are 'permeable to new ideas and experiences' and 'motivated to enlarge their experience into novel territory'" (DeYoung *et al*, 2005: 1459). Hopefully additional research designed to test similar hypotheses will be approved, and help to shed more light on whether or not a transformation of consciousness could be triggered by psychedelic experience. MacLean *et al*. (2011: 1459) cautiously agree, telling us:

> Although the findings are suggestive of personality changes that might be associated with hallucinogen[7] exposure, it is not possible to isolate the effects of hallucinogens per se because of the self-selection bias that may confound results of cross-sectional studies. Longitudinal studies will be required to replicate hallucinogen-related changes in personality, attitudes, and values.

Their initial research findings support Metzner's same echo of hope:

> The potential of psychedelic drugs to act as catalysts to a transformation into *gnosis*, or direct, ongoing awareness of divine reality, even if only in a small number of people, would seem to be of the utmost significance. ... the discovery of psychedelics, in facilitating such experiences and processes, could be regarded as one very important factor in a general spiritual awakening of collective human consciousness (p. 81). ... The knowledge derived from altered states has been, can be, and needs to be applied to the solution of the staggering problems that confront our species (Metzner, 1989: 88).

Beyond this introductory discussion, to make sense of the context within which MacLean *et al*'s clinical research apply - as well as the concerns expressed by Mitchell, Prattis, Getty, Ram Dass, Seed, Roszak, Gomes, Grof, Krippner and Metzner - and gain a broader understanding of how the concept of "internal pollution" emerged, requires sorting out and framing the historical development out of which ecopsychology emerged.

Ecopsychology's roots in humanistic & transpersonal psychology

I see the resignation of nothingness
I hear the repercussions of pointlessness
I'm completely torn
My whole attitude bears my scorn.
I hear the silence of another day
While our existence gets wiped away,
You know the games that we all play.
I see you're playing with my tolerance,
Gotta rise above this consciousness.

- Tim Masters, Lincoln, Nebraska, 1997

When the confluence of events that eventually lead to the birth of both humanistic and transpersonal psychology (and eventually ecopsychology) were being sown, I was four years old. Greenway has generously contributed to my understanding of this early history, recalling (in one of our many email exchanges from 2001-2010) that one rainy afternoon in late fall 1962, Abraham Maslow was looking out the window, saying, "It's not enough, humanistic psychology is not enough". This initiated Maslow's thinking about the limits of humanistic psychology, and it was during this time that he became influenced by Sir Julian Huxley's view of transhumanism (1957). Another four years would pass until the next break-through would come, as Anthony Sutich (1969: 13) tells us: "In January, 1966, several members of the Board of Editors of [*Journal of Humanistic Psychology*] were invited to a seminar titled 'Humanistic Theology' with Father [Patrick] MacNamara". Maslow was among the participants in this seminar, who afterwards developed its inquiry through an exchange of letters with Sutich. Sutich adds (p. 13) that "Early in January 1967, the term 'Transhumanistic' ... became the key word for this force".

And yet further clarification was still needed, as Miles Vich (1988: 107) points out, that the name for this new frontier did not come without some initial floundering. Maslow was among the first to use the term "transpersonal" in a communication to Sutich in 1967, and again in 1968 in a letter referring to a meeting with Grof:

> The main reason I am writing is that in the course of our conversations we thought of using the word transpersonal instead of the clumsier word transhumanistic or trans-human. The more I think of it, the more this word says what we are all trying to say, that is, beyond individuality, beyond the development of the individual person into something which is more inclusive than the individual person, of which is bigger than he is (Sutich, 1967).

This reference to something bigger, more inclusive, or whole than the individual person, is the creative insight that motivated Maslow to investigate what he called peak-experiences (Maslow, 1964), and harks back to Hofmann's nature experience at age nine that provided him with a way to integrate and internalize his first accidental LSD experience.

It would require a more careful analysis of humanistic and transpersonal psychology's early history (beyond the limited one provided here) to learn if any of its members, or MacNamara, was at this time influenced by the clarion call of Lynn White, Jr., who (the same year as MacNamara's pivotal seminar) boldly criticized the Western form of Christianity in 1967 as "the most anthropocentric religion the world has seen" (White, 1973: 25). Summing up his argument, White asserted: "Both our present science and our present technology are so tinctured with orthodox Christian arrogance toward nature that no solution for our ecological crisis can be expected from them alone. Since the roots of our trouble are so largely religious, the remedy must also be essentially religious, whether we call it that or not" (pp. 29-30). Metzner has criticized "the minor inelegance of [anthropocentrism,] a term of mixed Greek and Latin derivation" (Metzner, 1991: 148), suggesting instead the "diagnostic metaphor the *human (or humanist) superiority complex*" (Metzner, 1999: 84).

Additional memories of this early history were provided by Krippner, who recalled in his last conversation with Maslow that Abe spoke of founding a new psychology he was calling trans-human psychology: "We should therefore extend our concerns - go trans-human - and not make this a human-centered psychology" (Schroll *et* *al*, 2009: 40). Krippner added, "As we talked about it, in retrospect, I now realize he was talking about what we now call ecopsychology" (Schroll, 2008/2009: 16). "Unfortunately Maslow never had this dream realized" (Schroll *et al*, 2009: 40); summing up his views on this recollection, Krippner added the opinion "that ecopsychology is [now] absolutely critical" (p. 46).

To recreate in our awareness the turbulent social psychological context within which both humanistic and transpersonal psychology emerged, let's recall one of the most shocking images of our twenty-first century selves that came screaming into our lives: the stark vocals of the song *21st Century Schizoid Man*, whose lyrics explode with a rant characteristic of the 1960s revolution in sound, presentational style, and content:

Cat's foot, iron claw,
Neurosurgeons scream for more
At paranoia's poison door
Twenty-first century schizoid man.
Blood rack, barbed wire,
Politicians' funeral pyre
Innocents raped with napalm fire
Twenty-first century schizoid man.
Death seed, blind man's greed,
Poets' starving children bleed,
Nothing he's got he really needs,
Twenty-first century schizoid man.

These are the words and poetic illuminations of Peter Sinfield, whose inspirations in 1969 flayed our skins, and burned these thoughts into our brains, assisted by the searing blast of controlled fusion known as the musical group *King Crimson*. Sinfield's chilling reference to the schizoid personality type continues to loom large on the horizon of humankind's future, warning us to wake up from our dissociation from self, society, and nature, because the schizoid person is no longer in touch with their feelings. Instead, the schizoid person lives in a state of psychological disconnection from other people and the world of nature. All of us are in danger of becoming this schizoid man (Schroll, 2008/2009: 16-7).

This schizoid man is what Metzner refers to in his book *Green Psychology* as "the collective psychopathology of the relationship between human beings and nature" or, in other words, "dissociation" (Metzner, 1999: 94-97). Psychology should therefore be on the front lines of the endeavor to examine our worldview, and ourselves, but mainstream psychology is currently dominated by technophiles. These technophiles, or perhaps more poignantly necrophiles, actively encourage technology's consumptive behavior and instrumental use of nature (the systematic transformation of nature into its use by humans)[8].

1969 witnessed the *Association for Transpersonal Psychology*'s birth, whose inception found inspiration in Maslow's 1968 vision that "without the transcendent and the transpersonal, we get sick, violent, and nihilistic, or else hopeless and apathetic" (Maslow, 1968: iv). Recognizing this, it is hard to say whether psychology was influencing pop culture or if pop culture was influencing psychology, because in 1969, Alan Watts was also describing the emotional autism of Seinfeld's 21st century schizoid man in *Does It Matter?: Essays on Man's Relationship to Materiality*, telling us that:

> ... People, whether Western or Eastern, need to be liberated and dehypnotized from their visions of symbolism and, thereby, become more intensely aware of the living vibrations of the real world. For lack of such awareness our consciousness and consciences have become calloused to the daily atrocities of burning children with napalm, of saturation bombings of fertile earth with all its plants, wild animals, and insects (not to mention people), and of manufacturing nuclear and chemical weapons concerning which the real problem is not so much how to prevent their use as how to get them off the face of the earth. [If we can ever hope to survive this madness, we will] need to become vividly aware of our ecology, of our interdependence and [our] virtual identity with all other forms of life (Watts, 1969: xiv).

Watts could have written these words yesterday, and we owe it to his and Maslow's legacy to honor their vision and give birth to ecopsychology, and a transpersonal ecosophy. Equally poignant, as if it could be today's top news story, this prevailing spirit of dread, anxiety, and dissociation was eerily summarized in Roszak's *The Making of a Counter*:

> If the technocracy in its grand procession through history is indeed pursuing to the satisfaction of so many … universally ratified values as The Quest for Truth, The Conquest of Nature, The Abundant Society, The Creative Leisure, The Well-Adjusted Life, why not settle back and enjoy the trip? The answer is, I guess, that I find myself unable to see anything at the end of the road we are following with such self-assured momentum but Samuel Beckett's two sad tramps forever waiting under that wilted tree for their lives to begin. Except that I think the tree isn't even going to be real, but a plastic counterfeit. In fact, even the tramps may turn out to be automatons … though of course there will be great, programmed grins on their faces (Roszak, 1969: xiv).

Is "this discovery that we are nothing more than soulless creatures playing the starring role in some theater of the absurd really the image of the world and the future that we have all be waiting for? It is certainly not the vision of the future I have been waiting for, yet before any of us slips into some kind-of deep depression about this dismal prediction of the future - it is important we call to mind that "if" is the key word in Roszak's scenario of the future. That is, if the resistance of the counter culture fails, … if we fail to transform our present crisis of perception into an opportunity for transformation... If we do not become active in the political process needed to create better communities, if we neglect the cultivation of our transpersonal growth" (Schroll, 2008/2009: 17), then yes our future looks bleak.

Flash forward 27 years to hear again how these concerns continue to impact our understanding of science, culture, our collective future, and those of transpersonal psychology in particular, as David Fontana and Ingrid Slack persuasively argued in their paper "The need for transpersonal psychology":

> In an increasingly shrinking and independent world, it therefore seems vital that Western scientific psychology [begin an active exploration of] the influence that transpersonal experiences and beliefs have upon human motivation and behaviour. Such exploration must also take in the extensive and culturally important formal psychologies generated by non-Western traditions, the majority of which have their basis in, or make reference to, alleged transpersonal experiences. … The very future of mankind (a grand phrase, but not inappropriate in the circumstances) depends increasingly upon international understanding, and if Western scientific psychology is to play a role in this understanding … it would therefore seem imperative that it make its presence felt in the areas concerned without delay (Fontana & Slack, 1996: 4).

Fontana and Slack's call to action led to the formation of a Transpersonal Psychology Section in the British Psychological Society, whose concerns parallel similar conversation taking place within the current paper, and ecopsychology as a whole. To foster further synthesis between these conversations it is therefore important to acknowledge limitations within our view of transpersonal psychology.

Recognizing the limitations of transpersonal psychology

Tried so hard, but I just can't relate
Is it mind control, or just a separate state?
I see millions of people moving to the right,
Afraid of one another, afraid of the light.
Yuppie vermin consumers, a generation lost,
When up pops another breathing their exhaust.
It's dawn of the dead, or zombie land,
While new abuses of power are seen throughout the land.
Our seas are filled with oil,
We worry about burned flags,
All these contradictions are really such a drag.
So keep those closed minds humming
Bolting down the screws,
These complicated questions
Are a new case for the blues.
- Jim Jacobi, Seattle, Washington, 1998

Much of the theoretical basis for transpersonal psychology has been constructed from the religions and psychologies of Asia: Hinduism, Taoism and Buddhism. Even though I spent five years studying Zen Buddhism and attempting to practice its meditative methods, the feeling of treading on (or infringing upon) foreign soil was always present. Despite this somewhat unnatural feeling that always crept into my experiential encounters with Zen, and my theoretical study of the religions and psychologies of Asia, Maslow's founding spirit of transpersonal psychology continues to hold a hope for me. I continue to find that the Hindu myth of the universe resonates in my own unconscious and my psilocybin inspired experiential cosmology (Schroll, 2004a). Taoism provides philosophical insight (Kasulis, 1981), and Zen koans unify my body/mind (Schroll, 2011b)[9].

Nevertheless, the limitations of transpersonal psychology (especially the possibility of enlisting its help in expanding EuroAmerican ecopsychological awareness) became shockingly evident when I read Philip Novak's (1987) paper "Tao how? Asian religions and the problem of environmental degradation". These include: (i) The case of India; (ii) The case of China; and (iii) The case of Japan. Beginning with India, Novak reveals the discrepancy between Hinduism's theoretical teachings and the daily behavior of its practitioners:

> The Vedic literature repeatedly expresses a vivid appreciation of and deep reverence for Nature. [Yet n]othing illustrates more vividly the paradoxical nature of India's relationship to the environment than the condition of the Ganges. ... It is estimated that 'at least 10,000 half-burned bodies are tossed into the river every year either at Varanasi or towns upstream. Whole leprous corpses are often thrown into the river by ignorant townsmen who fear that burning would spread the leprosy bacilli in the air through the smoke. Benares alone dumps 20,000,000 gallons of raw sewage into the river every day. One huge sewer pipe empties into the river only 100 yards upstream from the city's main drinking water intake pipe' (Novak, 1987: 33-6).

Those of us familiar with Hinduism know that the Ganges is sacred to Hindus, who believe its waters are holy and purifying. Each year thousands of Hindus make pilgrimages to the Ganges to bath in and drink its sacred water. This certainly speaks to the power of ancestral wisdom; it also speaks to the power of denial.

Second, Novak proceeds to talk about China. Telling us that throughout China's history the behavior of the spiritual practitioners of Buddhism and Taoism has resulted in many devastating effects on the natural environment:

> Even Buddhist monks share the blame. [René] Dubos notes that they used enormous amounts of timber for the construction and constant reconstruction of their halls and temples, [resulting in widespread deforestation,] and that despite their supposed vegetarianism, kept livestock which overgrazed the surrounding lands. ... Dubos wryly suggests that the famed Chinese attitude toward Nature arose as a response to the environmental damage done in antiquity, and that we owe our romantic notions of Chinese reverence for Nature to the writings of retired bureaucrats who lived on estates where Nature was systematically submitted to the pruning shear (Novak,

> 1987: 36).

Novak goes on to add that the ink, with which the beautiful calligraphy of Buddhism and Taoism was traditionally drawn, came from the soot of trees. But cutting down a full grown tree is a labor intensive task, so monks eventually adopted the practice of using small saplings to obtain the ash for their ink. This practice of course added to the deforestation of China, while Buddhist and Taoist monks wrote beautiful calligraphy about nature with this ink: bringing to mind the colloquial phrase, *is there something wrong with this picture*?

Third, during the 1989 conference "Gaia Consciousness: The Re-Emergent Goddess and the Living Earth" (organized by James A. Swan), Novak followed up his 1987 criticisms of Asian religions; specifically the profound contradiction of Asian religions actual treatment of Nature with that of their professed worldview. Adding one more nail in the coffin, Novak writes:

> Up until 1970, when a number of stringently enforced environmental laws were passed there, Japan, largely because of its post war industrial push, had become the *Itchiban*, the number one industrial polluter in the world. Japan Scholar, Edwin Reischauer, said that the Japanese have done more than any other people to defile nature, though no people love it more (Novak, 1989: 51).

Meanwhile, as the people and corporations of Japan continue to clean-up their act at home, the Mitsubishi Corporation (and related groups) are contributing to an alarming rate of deforestation. According to the EcuadorExplorer.com (2013), this planet-wide rate of deforestation equals 86,000 hectares per day, an area equivalent to New York City. This breaks down to 1 hectare (2.4 hectares) per second, or two U.S. Football fields, 31 million hectares per year, an area larger than Poland. Novak reminds us that while the homeland of Japan is sacred to the Japanese, the rest of the world is perceived as a frontier that is wide-open for corporate development.

In summing up these examples of transpersonal psychology's limitations, I want to reiterate that I continue to believe the traditions of Hinduism, Taoism, and Buddhism are capable of providing us with valuable sources of wisdom that can assist us in reestablishing our lost connection with the nonhuman world. Nevertheless, these examples serve to illustrate the fact that just because we become a practitioner of these traditions does not automatically guarantee that our attitudes and behavior will be transformed regarding our relationship toward all natural systems. Moreover, these examples also serve to demonstrate that even if we become practitioners of Hinduism, Taoism, and Buddhism we may still find ourselves falling-victim to the effects of what Kremer and Donald Rothberg call our collective shadow:

> We can define the collective shadow as the unknown or little-known aspects of a society and culture [that continue to remain hidden in our unconscious because of voices emanating from] ... dominant discourses (Kremer & Rothberg, 1999: 3).

Elaborating on this concern, Rothberg has begun the task of bringing these limitations of Asian psychologies and religions to the attention of the transpersonal movement, telling us:

> ...it is important to ask critical questions about the extent to which the transpersonal field has given a selective reading of spiritual traditions and highlighted some kinds of spiritual expression rather than others. ... While the idea of a 'perennial philosophy' and an emphasis on contemplative and mystical traditions, particularly Asia, has broadened contemporary Western understandings in philosophy and psychology tremendously, it remains vital to ask whether certain aspects of human development are also brought to high levels in other kinds of traditions[?] (Rothberg, 1999: 46).

Rothberg goes on to point out that what has been missing from the transpersonal field is a consideration of the importance of "the indigenous traditions of all continents" (p. 46). He offers a brief mention of "African-Christian Voodoo in Haiti, which played a pivotal role in gaining Haitian political independence at the end of the eighteenth century" (p. 57), yet overlooked in his otherwise thorough assessment is Molefi Kete Asante's (1984) paper "The African American mode of Transcendence". Asante provides the insight that "*Samba* the Brazilian dance, *Sango* the Cuban folk religion, *Umbanda* the Brazilian folk religion, *Voodoo* the Haitian folk religion, or *Myal* a Jamaican religion" and the African idea of Sudicism all have the "same source of energy, the rhythm or polyrhythms that drive the spirit toward transcendence" (p. 168). It is an internalized resonance with the groove of percussion sound and movement that gives expression to the African American holistic personality, and can be accessed "in any good blues or jazz club [where] you can get the same soulful sound as you get in the church" (p. 176). This source of transpersonal wisdom is especially consistent with that of ecopsychology or transpersonal ecosophy, as Asante makes clear: "it does not depend upon icons of faith but the incessant collective drive of people for harmony with self, fellow earthlings, and nature" (p. 176). This view is consistent with, and supportive of, my own life-long inspiration through blues and rock music, including its storytelling capacity through powerful lyrics such as I have used in this paper.

Metzner too shares Rothberg's concern with other traditions missing from the transpersonal field, which led him to explore the indigenous roots of his Germanic ancestry in *The well of remembrance: Rediscovering the Earth wisdom myths of Northern Europe* (1994). In pursuing this inquiry, Metzner raised the question: "Those of us descended from European ancestors are naturally moved to ask whether anything in our own tradition is relevant to surviving the ecological crisis. This book explores the animistic-shamanistic worldview of the aboriginal inhabitants of Europe" (Metzner, 1994: 1-2). Through his thorough inquiry, he convincingly demonstrates that "shamanic otherworld journey practices [are] at the very heart of the religious worldview of the ancient Germanic people" (p. 198). Therefore those of us who are descended from Germanic (including Anglo-Saxon) and Celtic peoples of Northern Europe who are often criticized for borrowing, intruding upon, or stealing the wisdom of indigenous peoples can now answer back that this is our tradition too.

This analysis of the Earth wisdom myths of northern Europe concludes in Metzner's final chapter with his discussion of the eschatological myth of the Ragnarok, which he explains "is usually translated as the 'twilight of the gods', but more precisely means 'final fate of the gods'" (Metzner, 1994: 244); and calls to mind for most of us an apocalyptic vision where the forces of evil destroy the world, leaving the Earth a barren and uninhabitable place - thereby necessitating a new kingdom of Heaven, which is sent down to earth by God. Yet, according to Metzner, this interpretation completely misses the point that the Ragnarok is trying to teach us; instead he draws our attention to the fact that this final battle does not involve all of the gods. Much to the contrary, it is only the warrior oriented Aesir sky gods that are involved in this cataclysmic earth transforming battle, which Metzner explains is followed by "a renewal of the Earth and a new beginning of life, with a new generation of gods and humans telling stories and remembering ancient knowledge. 'A new green earth arises again out of the flood'" (pp. 249-50).

Consequently the peace-loving Vanir nature gods and a new generation of humans who were absent from this battle are left to re-inherit the earth. In other words, the final fate of the gods calls to mind a vision of "worldviews in collision", symbolized by a battle between logos-oriented male heroes and the forces of nature they have sought to dominate and control. Today these groups are represented by technocracy and its oppression of both humankind and the non-human world. This is a good point on which to end this discussion from both a substantive perspective, and because we have gotten ahead of ourselves in this autobiographical chronology.

Shamanism and the neo-shamanic revival

> In 1989 Walsh published a series of articles on shamanism in the *Journal of Transpersonal Psychology* and *ReVision* (Walsh, 1989a, 1989b, 1989c)[10]. Immersed in this literature, I was invited by Stephen Glazier to organize a symposium on shamanism for the 1990 *Society for the Scientific Study of Religion* (SSSR) conference, held in Virginia Beach, Virginia. I accepted this invitation, motivated by the theme of creating a symposium to deepen our commitment toward envisioning a technology of transcendence or a renaissance of mysticism with an ability to produce the necessary transformation of consciousness to awaken a heart-felt response to the ecocrisis. Clarifying this idea in a marginal note in Larry Peters article 'Shamanism: Phenomenology of a Spiritual Discipline' (Peters, 1989), I wrote, it will [only] be through an authentic cultivation of *communitas* and the deep ecology movement that we will be able to transcend our presently destructive interaction with nature, and, thereby, transform our presuppositions about reality (Schroll, 2011a: 29).

This reflection reminded me that Joan Townsend had expressed a similar viewpoint:

> Periods of religious enthusiasm are not uncommon in the history of the Western World. This latest trend seems unusual, however, and distinct from earlier religious movements such as the Great Awakening of the 1740s and the Second Great Awakening after 1790 in the United States, because it combines a number of different systems of belief and is fostered by a network of individuals sharing a communication system that is unprecedented ... this new mystical movement owes its initial definition to the 'hippie' and related movements that began in the 1960s. ... Characterized by the search for a new meaning in life, ... a feeling of kinship among all people. ... and the valuing of simple, 'natural' lifestyles and conservationist concerns. Significantly, there were also a strong interest in nonorthodox theologies, especially spiritualist, mystical, and Eastern religious philosophies, as well as native American culture, including shamanism (Townsend, 1988: 74) (quoted in Schroll, 2011a: 30).
>
> Townsend referred to this movement as *neo-shamanism*, adding 'important to the development of neo-shamanism in the West were Michael Harner's work. ... [and] the publication in 1969 of Carlos Castaneda's doctoral dissertation in anthropology... Thus by the early 1970s the stage was set for the rise of neo-shamanism' (Townsend, 1988: 75).

Here I must interject: at this phrase of inquiry I had yet to organize the symposium "Castaneda's controversy: Examining consciousness studies' future", which took place April 3, 2003, at the 23rd Society for the *Anthropology of Consciousness* conference. This attempt to understand contemporary culture and provide some analysis is discussed in Schroll, 2010a, whose inquiry is deepened in Schroll, 2010b.

Flashback to 1990 - inspired by the shared sense of vision in this passage with my own, I telephoned Townsend on April 20, 1990, to discuss these ideas. Our conversation convinced me we were moving in the same direction, suggesting an elaboration on her work might be titled "Authenticity and Delusion: Shamanism and Neo-Shamanism" (Townsend, 1990). She agreed, accepting my invitation. Another important contribution "Personal Reflections on My Journey into Shamanism" emerged through my phone conversations with Michael Schneider. This was his first public discussion of a life-threatening illness and miraculous recovery that called Schneider to become both a Certified Shamanic Counselor and a close associate of Harner. Prior to his illness and recovery, Schneider had been a New York City ad man (Schroll, 1990). Schnider's personal story provided additional anecdotal testimony of the influence transformations of consciousness have on the way we lead our lives.

The continuing resurgence of this interest in shamanism was raised again five years later, when in her chapter "Shamanic Counseling and Ecopsychology", Leslie Gray concluded: "It would be tragic to waste this accumulated [indigenous] knowledge, and it would be redundant for ecopsychology to generate models of a sustainable future without learning from the way of life of the more than 300 million indigenous people living in the world today" (Gray, 1995: 182). Krippner supports this view (2002).

Summing up shamanism's critical importance to our inquiry in ecopsychology and transpersonal ecosophy, and offering insights she and I developed through our correspondence following our meeting at the 2004 symposium I organized on "Psychedelics: Their Value and Social Responsibility" (Schroll, 2004b), Maura Lucas illuminates the concerns facing us:

> Cultural anthropology has long been in a difficult place, feeling the squeeze between postmodernism on the one hand, with its point that there can be no analysis of another culture that does not contain one's own culture and personal preconceptions, and biological anthropology on the other hand, claiming that if anthropology is subjective, then anthropologists should rely on hard, empirical data for the study of humanity. The point of [Jeremy] Narby's and [Francis] Huxley's edited book *Shamans Through Time* (2001) is that Western anthropologists have always seen shamanism through the lens of their own preconceptions. Anthropologists looking at shamans and interpreting their experience are not objectively describing shamans or shamanism, but coming to a kind of subjective middle ground between what they have observed, and their own culture's ideas at that point in history. If there can be no objective understanding of shamanism, then it makes sense for anthropologists to debate what constitutes appropriate expertise for writing about shamans and psychedelics (Lucas, 2005: 49-50).

Nevertheless, once again I am getting ahead of myself, as it was actually several months before I convened the 1990 symposium on shamanism that another significant break-through took place.

A breakthrough in 1990: Continuing to trace transpersonal ecosophy's many paths

There's colors on the street, red, white and blue
People shufflin' their feet, people sleepin' in their shoes
There's a warnin' sign on the road ahead
There's a lot of people sayin' we'd be better off dead
Don't feel like Satan, but I am to them
So I try to forget it any way I can.
We've got a thousand points of light for the homeless man
We got a kinder, gentler machine gun hand
We got department stores and toilet paper
Got styrofoam boxes for the ozone layer
Got a man of the people, says keep hope alive
Got fuel to burn, got roads to drive.

- Neil Young, 1989

In Spring 1990 two significant papers were published: Fox's paper, "Transpersonal ecology: 'Psychologizing' ecophilosophy" and Metzner's, "Germanic mythology and the fate of Europe". I began corresponding with Fox sometime in June of 1990. In August, I read in Harner's *Foundation for Shamanic Studies Newsletter* that Metzner was forming the Green Earth Foundation:

> Through its projects, the Green Earth Foundation aims to help bring about changes in attitudes, values, perceptions, and [our] worldview that are based on ecological balance and respect for the integrity of all life forms on Earth. Specifically, this involves re-thinking the relationships of humankind with the animal kingdom, the plant kingdom and the elemental realms of air, water and earth/land (Metzner, 1992).

Becoming a member of the Green Earth Foundation I soon began a correspondence with Metzner. Through our correspondence, Fox and Metzner agreed to serve as dissertation supervisors on my doctoral committee through The Union Institute. During this time, Jeremy Hayward, vice president of the Naropa Institute (now Naropa University) and editor of Shambhala's New Science Library, edited Fox's doctoral dissertation, which was published in the summer of 1990b. Eugene Hargrove, editor of *Environmental Ethics*, noted in a media blurb that Fox's "*Toward a Transpersonal Ecology* ought to be read not only by supporters of the deep ecology movement but also by its critics. It is destined to be a classic in the field".

I agree, Fox's book continues to be a classic in the field and a rich source of information to assist our understanding of the deep ecology movement's relationship with transpersonal psychology. Still, when Drengson informed me that Naess had suggested to Fox that "Toward a transpersonal ecosophy" would have been a better name for his book, I began to wonder why in the four years Fox served as one of my dissertation supervisors (2/9/91 - 1/29/95) that he never mentioned this to me? Perhaps one day this and other important questions about ecopsychology and its transition into transpersonal ecosophy will be answered. These and other questions will need to wait for future papers, even though (except for occasional references to my more recent work), this autobiography stopped short of discussing my present activities by more than ten years.

Conclusion

They can domesticate music, they can do most anything,
They can teach us how to dance, they can teach us how to sing,
But you can't tame a real wild thing.
- Jim Jacobi, Lincoln, Nebraska, 1999

The "they" in Jacobi's song refers to the technocratic paradigm, and its widespread influence on the humanities, natural and social sciences. It was Roszak's concern with technocracy, as I pointed out at the beginning of this paper, that motivated him to write his book *The Making of a Counter Culture* (1969), and this has been a recurring theme in all of Roszak's work. This paper, if successful, sought to provide an autobiographical overview of ecopsychology, and its transition to transpersonal ecosophy. Psychedelic experience (its historical influence on elders such as Krippner, Metzner and Grof), MacLean, *et al*'s clinical investigation of psilocybin, as well as anthropologists of consciousness (Beyer, Harrison, Tindall, and Webb) are contributing to transpersonal ecosophy's emergence. Further inquiry is needed, and for better or worse, pro or con, this paper offers us a place to start. Here too I recall my memory of conversations with Hofmann at the "Worlds of Consciousness" conference (at the University of Heidelberg, Germany, on February 22 and February 25, 1996), and a group of German graduate students on February 24, 1996.

Pointing to the Necker river which was the predominant feature of nature that could be witnessed from the second floor window of Stadthalle (where the "Worlds of Consciousness" meeting was held), I explained that the resource preservationist might variously proclaim: Oh the river, it is so beautiful and inspiring! It must be preserved (the art gallery/cathedral argument). Oh the river, I love to sail my boat on it (the gymnasium or health club argument). The river, it has so many valuable forms of life that it sustains, it must be preserved (the silo argument). The river is my special friend, and is essential to my way of life, because I am a farmer and I use the river to sustain my crops in times of drought (the life support system argument). These were paraphrased statements based on my memory of Fox's examples in *Toward a Transpersonal Ecology* (1990b). Each of these arguments for preserving the river transforms it into an object for human use. Our cries of concern to preserve the river have the appearance of championing the concerns of the non-human world, and yet, the source of our alarm is our own self-interest. This is not a criticism of our actions, but merely an observation to raise into our awareness what our actual motivations are, and acknowledge them. Whereas to be aware of the river's essential nature allows us to realize, *the river simply is*. It does not exist for you or I, it exists for its own sake. Raising this question, how can we meet our human-centred needs, and balance these with our co-evolution with nature and the cosmos? Developing this way of knowing is the concern of transpersonal ecosophy.

Finally, summing up my views on psychedelics (and as a way of referring to my more recent work), the view I have sought to convey in this paper is that:

> psychedelic experience provides us direct access to universal archetypal truths that transcend the boundaries of culture and the limitations of spacetime. Psychedelic experience allows us to encounter visionary mystical insights about the human condition, Gaia consciousness, and deep community and cosmic unity. Psychedelic experience is a fundamental awakening to self-realization (and Arne Naess talks about self-realization being an aspect of personal philosophy - which he called Ecosophy-T - within the deep ecology movement). Psychedelic experience is not the culmination of personal growth and transcendence; it is instead the beginning of the questioning process. Psychedelic experience is the root and ground from which our investigation of the big cosmological picture begins. Psychedelic experiences is the tree from which the fruit of myths and metaphors of consciousness grow. Eliminating psychedelic experience violates the open scientific inquiry of radical empiricism. Without psychedelic experience, religion ossifies into ritualistic symbolism without somatic significant understanding. Psychedelic experience is the very essence of transpersonal psychology, and [its source of wisdom] the primordial tradition. Recognizing this will require us to examine our personal and collective shadow and the reasons for why we are here (Schroll & Rothenberg, 2009: 43).

Acknowledgements

Ralph Metzner's observation that I "may be the first transpersonal cultural theorist drawing on pop songs to illustrate collective images" has been illustrated with my use of rock lyrics in this paper. Metzner's encouragement for my assessment of both his own work, and my interpretation of ecopsychology, lead to the current paper. The encouragement of Stanley Krippner, and more recently Alan Drengson, to clarify my own interpretation of ecopsychology has motivated the current paper's contribution to this body of knowledge. The current work has also benefited from its early development of these ideas in *Association for Humanistic Psychology-Perspective, International Journal of Transpersonal Studies, The Trumpeter: Journal of Ecosophy*, and *Paranthropology: Journal of Anthropological Approaches to the Paranormal*. David Luke's invitation, The European Journal of Ecopsychology, and its blind reviewers, were essential in producing this paper.

Footnotes

1. See Schroll, Krippner, Vich, Fadiman & Mojeiko (2009). Metzner (1999: 169-70) echoed this view. See also Krippner & Luke, 2009; Metzner, 2008, 2009; Schroll, 2009b.
2. For a comprehensive inquiry of shamanism see Walsh (2007). My use of the word "shamanism" (which includes my use of the word "shaman" throughout this paper), is consistent with Peter N. Jones linguistic and phenomenological inquiry. Specifically:

   > The term shamanism defines a phenomenon that occurs among only a select few individuals (the "shamans") at any given spatiotemporal moment, and that operational definitions of the phenomenon must be limited to those specific spatiotemporal moments; and... only a nominal definition is possible when discussing the phenomenon diachronically or cross-culturally, and this nominal definition is contingent upon ethically understood notions of the folk epistemology and folk ontology of the cultures compared... : shamanism is a phenomenon consisting of an individual who has voluntary access to, and control of, more aspects of their consciousness than other individuals, however the components of that consciousness are emically understood, and that this voluntary access is recognized by other members of the "shaman's" culture as an essential component of the culture (Jones, 2006: 21).

   Understandably Jones' strict definition of shamans and shamanism is a response to the widespread phenomenon of neo-shamanism (Townsend, 1988, 1990) that we shall discuss later in this paper. Yet it is important to point out non-Native's and non-shamans have been shown to experience transpersonal states in sweat lodge ceremonies (Hibbard, 2007).
3. Psychedelic has been defined, as Metzner (2004: 4) tells us, by "Humphrey Osmond, the English psychiatrist who pioneered the use of LSD in the treatment of alcoholism and who gave Aldous Huxley his first mescaline experience, coined the term *psychedelic* ('mind manifesting'). This term was adopted by the Harvard psilocybin research projects". David Luke further clarifies the use of this term, telling us: "A psychedelic substance, as opposed to other substances, has been defined as that 'which, without causing physical addiction, craving, major psychological disturbances, delirium, disorientation, or amnesia, more or less reliably produces thought, mood, and perceptual changes'" (Luke, 2011: 357-8).
4. Lajoie and Shapiro have examined 202 original citations pertaining to transpersonal psychology (1992). Contemplating these lead to my own definition: "The transpersonal is equally present in states of ecstasy, sensuality, and somatic experiences that are capable of just shaking you to your roots and really waking you up: life encounters that make you come alive and experience the kinesthetic, the tactile, and the erotic. Each of these human drives (and their various nuances) is equally important toward the creation and maintenance of a healthy personality. Nevertheless, no definition of transpersonal psychology should be viewed as a description of some finished or final product of enlightenment. Rather, transpersonal psychology's emphasis is on the continuous process of transcendence and transformation within the realms of the personal, the planetary, and the cosmological" (Schroll *et al*, 2011: 125).
5. Two examples of my support for conservation biology and resource management are: (i) On May 14-15, 1990, I served as a volunteer forester at Fort Robinson State Park, near Chadron, Nebraska, during which I planted 200 seedlings of *ponderosa* pine. Fort Robinson has the ominous legacy of being the place where the Native American tribal leader and shaman Crazy Horse was shot in the back while purportedly escaping, yet the door to his cell had conveniently been left open. (ii) In November of 1997, I attended an annual conference sponsored by Pheasants Forever in Grand Island, Nebraska. During a workshop facilitated by the Nebraska Game and Parks Commission that dealt with the concern of preserving habitat, I articulated the idea of treating the symptoms versus getting to the ecopsychological origins of these symptoms. Not only did the farmers and ranchers attending this workshop grasp the importance of this concept, this idea was published in the Nebraska Game and Parks Commission newsletter as a central concern toward guiding the considerations of future policy and planning of habitat restoration.
6. I have referred to "this opposite nullifying influence of trauma as the reliance on the fear approach or the rhetoric of catastrophe, the guilt approach or the rhetoric of shame, and the self-sacrificing/voluntary simplicity approach or the rhetoric of redemption as

negative motivating techniques" (Schroll et al 2009: 47).

7. Defining and sorting out the confusion associated with the word hallucinogen, Metzner tells us: The older term hallucinogenic ('hallucination inducing') was universally rejected by those investigators who had actually experienced these substances, since it was clear that they do not cause one to see hallucinations in the sense of illusions; rather one sees all the ordinary objects of the sense world plus another whole range of energies and phenomena normally not seen. However, etymology reveals that the original meaning of the Latin verb *alucinare*, from which 'hallucination' is derived, means to 'roam or wander in one's mind'. This is actually a fairly appropriate metaphor for the experience - a journey in the mind, in consciousness; a 'trip', as it became known colloquially (Metzner, 2004: 4).
8. See Schroll and Greenwood (2011) for a discussion of the 'Night of the Living Dead' model, which is our critique of technocracy that builds on Roszak (1969, 1999) and Drengson (2011). Likewise this paper further illuminates this reference to technophiles as necrophiles.
9. It is worth mentioning that Sufi stories provide invaluable pathways capable of reawakening our primordial ecological wholeness, in addition to serving as gateways into other ways of knowing (Schroll, 2011b; Schroll, Rowan & Robinson, 2011). See also Shah (1970). Sufism has some roots in Islam, as well as external influences, particularly from India.
10. During this same time I became increasingly influenced by the work of Michael Harner. His paper "The Role of Hallucinogenic Plants in European Witchcraft" (1973) is particularly relevant to our discussion of psychedelics and ecology.

Recollections of humanistic and transpersonal psychology's origin's morph into the pros and cons of humanistic/transpersonal oriented schools developing APA accredited clinical programs. This discussion dovetails with the question will ATP ever become an APA division, raising an interesting alternative for those of us considering a career in counseling: becoming a spiritual coach. Enter the issue of psychedelic therapy and the Supreme Courts decision to allow ayahuasca as a sacrament by the Uniao Do Vegetal Church, and the importance of why humanistic and transpersonal psychology need to clearly map out the territories and sub-divisions of science and religion. Finally this conversation raises a concern, that Maslow's call for a "trans-human" psychology sought to encourage creating what we now call ecopsychology.

This conversation forum took place on September 8, 2006, at the conference "100 Years of Transpersonal Psychology," in Palo Alto, CA, sponsored by the Association for Transpersonal Psychology (ATP) and the Institute of Transpersonal Psychology (ITP). Mark A. Schroll organized and served as the moderator of this forum asking Miles Vich, James Fadiman, and Stanley Krippner to reflect on transpersonal studies broad spectrum of inquiry, with additional reflection by Valerie Mojeiko on the current status of psychedelic studies. The discussion begins with some reflections on early meetings of humanistic and transpersonal psychologists in Anthony Sutich's home in Palo Alto.

The Early History of Humanistic and Transpersonal Psychology: Reflections on Tony Sutich's Living Room

Miles Vich: ... with characteristic energy and foresight he decided to write a documented account of his involvement in humanistic and transpersonal psychology. In June 1974 he formally began the necessary research for this project and contracted to write a dissertation on the subject as part of the requirements for a doctoral program in psychology at the Humanistic Psychology Institute in San Francisco. I used to joke with Tony as we were working on this project for a couple of years that he typically did things the long way around. Instead of getting the usual graduate degree somewhere, he waited a whole career-lifetime, formed a couple of fields, helped get some schools started, and then he got a degree from one of them. He brought this project to a successful conclusion when he completed his dissertation "The Founding of Humanistic and Transpersonal Psychology: A Personal Account." He received his doctoral degree April 9, 1976, one day before he died; and the three of us [Jim Fadiman, Stanley Krippner and I] were all there.

It is difficult to adequately describe or characterize this remarkable man; nevertheless it is necessary to recognize that thousands of individuals and many institutions have been influenced directly or indirectly by the efforts of this unusual human being. Tony Sutich's contribution is, among other things, an example of the value of what is humanistic, personal and transpersonal in our lives. If you go to the *Journal of Transpersonal Psychology* [*JTP*], you will see four or five articles [of his], and you will get a sense of what he says. His personal account, abbreviated to perhaps a dozen pages, is in *JTP* 8(1), 1976. I suggest you read Tony himself and get a sense of all the adventures that he had in this and related fields.

Stanley Krippner: Miles Vich has just given you a wonderful cameo presentation of Tony Sutich's life. The fourth member of his doctoral committee at Saybrook, formerly The Humanistic Psychology Institute, was Eleanor Criswell, who was also a leader in the transpersonal field and a real pioneer. When we went down to do his oral defense, he could barely speak; and yet he was so happy this work had been completed that it was a very joyous occasion. I went back home that night and had a dream. In the dream who should be coming in the door but Tony Sutich and he was walking. I said Tony this is the first time I have ever seen you walk. Tony said, "Oh I can do anything now I'm dead you know." This of course was the night he died.

His dissertation, on the founding of humanistic and transpersonal psychology is a classic: beautifully written, very articulate, and it was stolen from our files a few years later. Written in the days before computer files we thankfully were able to piece together a duplicate dissertation from a carbon copy. Just today Miles tells me he has discovered a pristine copy of Tony's dissertation. This discovery will be a cause for great rejoicing at Saybrook because now we can put it on microfiche and computer files, and it can be distributed more widely. Hearing the news of this discovery is really the highlight of my coming down to this conference today.

I should mention one other thing. Abraham Maslow was also a close friend of mine. He was talking about founding a new psychology the last time I saw him, that he was calling *trans-human psychology*. "As we talked about it, and in retrospect, I now realize that he was talking about what we now call ecopsychology" (Schroll, 2008/2009, p. 16). Because it stemmed from the deep ecology movement, the recognition (nearer to what Native Americans have believed for millennia) that humans as a species are just one of many species on planet Earth, maybe other planets too. "We should therefore extend our concern to them - go trans-human - and not make this a human-centered psychology. Unfortunately Maslow never had this dream realized" (p. 16), but other people like Theodore Roszak (1992) and Jeremy Narby (2001) have picked up on this idea, an idea we will be hearing more about in the future.

What Were the Experiences that Led Tony Sutich to the Transpersonal?

Mark A. Schroll: This brings me to several concerns. Let's pick up on when Tony had his mystical experiences, what triggered these? Did he take something? Was it natural? Do any of you know what caused him to have these mystical experiences?

Vich: Yes, we know a little bit about this. Some of this is in Tony's dissertation. Tony was always very modest about these discussions; its just he had a lifelong interest in these kinds of experiences and he read a lot. But I think too because he faced death so early, he was told he was going to die and then it didn't happen; this made him question everything. Likewise Tony would privately speak about his mother being such a positive supportive influence, yet his father was not quite as supportive. His family helped him through - this was the bottom of the depression when there was nothing out there; and this guy is on his back [Sutich was disabled by an accident at a young age and was unable to move for most of his life-], what does he do? So every conceivable question a person would ask was amplified in terms of being a crisis; everything had to be dealt with.

Tony too was just naturally brilliant and intellectually alive to all kinds of things. The other side of it in terms of psychedelics is something that Tony did not talk about much. All I know is from what he said; he said in print he had some experiences that were not particularly determining, powerful, or overwhelming. But they were in the line of other experiences that he had. You might call them mystical or spiritual or higher or a deeper psychology - it was broad. It has all kinds of cultural elements and all kinds of modes and vehicles; it was not just one channel it was many channels for him.

Schroll: Okay this was an important point. Another point I want to return to is that Tony then created a way to license himself. Could this possibly be a model for an alternative licensing board that would be an alternative to APA?[2] Can we reflect on this?

The Maturing of Humanistic and Transpersonal Psychology: Examining the Challenges of Academic Accreditation and Clinical Practice

Vich: Historically things are never the same. My two colleagues on the left here [Stanley Krippner and Jim Fadiman] are much more conversant with these issues. I have been out of the organizational, political and professional loop for a long time. But I will say it does not take much; it takes a particular idea, a particular action and a seed grows, but it is the later development where it affects lots and lots of people and the refinements occur. Consequently I do not know if what Tony did could be a model now. You would have to be in a kind of frontier situation where you had friends in the legislature; and then there are three of you in the whole damn state of California that cannot do anything except counsel. Then by a grandfather clause some political restrictions are overcome, and through some careful maneuvering the legislation comes out. But I do not think that things happen this way anymore.

James Fadiman: The issue of accreditation is always an interesting one. I was thinking of what you said Valerie - a little quiet throwaway line with your reference to "outlaw therapists" at Burning Man. Oh (the thought occurred to me), are there outlaw therapists? Well, there are people that have made a commitment to help human beings and they think that there is an unwritten law that trumps restrictive legislation that prevents any of us (that choose to) from helping human beings. This is true in mainstream psychology; it is true in transpersonal psychology. But it is not true in institutions. Institutions are highly visible; it is very hard to be an outlaw institution. Having been in a school where we began with the premise that we were an outlaw institution, we found the culture indeed accepted us as an outlaw institution and said, "You are not welcome anywhere."

Laughter from the gallery.

Fadiman: And there were very few similar kinds of institutions. I use a different term now, not outlaw but *outlier*, which means outside or near the edge. Whereas if you are leading, then you are known as avant guard; if you are simply at the edge and everyone moves in the other direction then they think that you are just a crank. Certainly as schools we've been dealing with this issue. The problem of accreditation of any sort (be it medical, psychological, nursing, massage, religious institutions) is you should be close to normal or close to the middle of whatever distribution of the family or group of ideas and practices you are attempting to represent. This is the task of assessment, and what accreditation represents. Accreditation never says that you are really terrific, interesting, exciting, and innovative. Or they say if you are, then you are not ready for us. But if you are vanilla, if you are interchangeable with other institutions, then you should be accredited. I'm not fond of accreditation, because being an outlier is more interesting, but that is the way it works. So that any institution which goes for accreditation has to see how it can at least appear to be vanilla before it gets accredited. Then fortunately once you are accredited, you are allowed to - changing metaphors here - to do a few things under the blanket that have a different point of view. I'm mentioning this because ITP - which, as Miles said, was not founded by Tony - at least he did not found everything...

Laughter from the gallery.

Fadiman: is looking to be accredited as a clinical institution by APA. The question is, this is good for people trying to earn a living, because APA is gradually controlling more and more state legislature's licensing rules.[3] But is it good for transpersonal? This is an entirely different question. Perhaps we will look at this.

Schroll: It is good in terms of the fact that to get paid by the insurance companies you have to be licensed. But it may not be good for philosophical reasons.[4] Tony was trying to help people - and as Valerie points out there are outlaw therapists that are also trying to help people. So how can you help someone and yet get paid?

Valerie Mojeiko: I don't really know that much about licensing, [so my question is this]. Currently people that are licensed as transpersonal psychologists - whether or not they are giving out illegal drugs - are not able to get paid by insurance?

Fadiman: If you are a licensed psychologist, there is not an adjective in front of that; its a licensed clinical psychologist, and whatever the restrictions on a clinical psychologist are, you have all of them. One of them certainly is that you are not allowed to prescribe drugs that are legal, let alone the more interesting ones.

Will Transpersonal Psychology Ever Become an APA Division? Wrestling with Spirituality and Organization

Schroll: This comment opens up the question of *ayahuasca*.[5] Earlier Stan Krippner mentioned the Supreme Courts decision to allow ayahuasca use as a legal sacrament.[6] This reopens the opportunity for psychedelic exploration. This also gets into the issue of moving psychedelic inquiry away from the medical model because we no longer need to be worried about the fact that we are either dispensing or ingesting a substance that could be regulated as a licensed medicine.

Krippner: Well in one church. Remember that only one church has the legal right to use ayahuasca as a sacrament right now. This brings up one of the advantages of a church organization because if you are a member of the clergy, you can give spiritual counseling. You do not have to call it psychotherapy; in fact you had better not call it psychotherapy. But just to avoid problems in the advice that I give people - in the secular trips I used to lead people on back in the old days - I became a minister for the Universal Life Church, and also for the Center for Spiritual Healing. I do wedding ceremonies; I'm doing one tomorrow, which is why I have to get back [to San Francisco] this evening to prepare. I perform weddings for people that want a typically unorthodox ceremony, where they can write their own vows, cite scripture from other traditions - such as Eastern, Native American, and even Wiccan traditions. If they prefer they do not even have to mention the word God, so what I do provides people with a meaningful ceremony, and I'm very happy to oblige.

Now the institutionalization of a movement is always a two-edged sword. On the one hand, accreditation does help a lot of people earn money because they get a more solid recognized degree. Some 30-years ago at Saybrook there was a group of faculty members that did not want accreditation; they said this would clip our wings, and ruin our freedom. We had state approval; they said state approval is enough as we are giving a legal degree. Others at Saybrook thought differently (I among them) and we won out and got Saybrook accredited, and we really did not have our wings clipped or anything like that; the same thing [came up] for ITP when it became accredited. But getting a program like a clinical psychology program recognized, that is a little different thing. Because if you are going to be a clinical psychologist, the way the zeitgeist is moving and the states are drawing laws, you have to be from an APA approved program.

Now I've been a member of APA for decades. APA has been very good to me, I'm a fellow of four APA divisions, and so I'm not critical of APA - except where I need to be like when they put too much emphasis upon their division of military psychology as they did at the last convention. But this is a whole other set of concerns that we do not have to go into right now. Anyway, APA has gotten to the point where they will give approval to an institution if it is solid and if it does what it purports to do.

I think that ITP has a very good chance of getting its [clinical] program approved by APA if they can convince APA that they've gotten their act together, that the therapists that come out of ITP are knowledgeable, that they can handle a variety of dysfunctional behaviors and attitudes. I know of some schools that the APA would not have approved 20 years ago that are now becoming APA approved. So the signs are favorable on this.

Nevertheless, getting an APA division called transpersonal psychology is an entirely different thing, and Mark wanted us to speak to this concern. There was a movement, 30-some-years ago, to have a Division of Humanistic Psychology. Most of my colleagues and I were against it. We asked, why do we need to create a division? Why not just have humanistic psychologists and transpersonal psychologists create their own associations, and then bring the humanistic flavor into already established APA divisions. The person spearheading this proposed Division of Humanistic Psychology was a radical psychologist named Don Gibbins, who went around and got the signatures, not from any of us, but from thousands of other people. Thus a Division of Humanistic Psychology in the APA was approved. We then got together for our first meeting and Gibbins wasn't even there; so we named one of the members of our group president, and the division has been going on ever since.

Was this a good thing? Not necessarily; because since this time Positive Psychology has come into the picture, and has sort of distanced itself from Humanistic Psychology.[7] If humanistic psychology had diffused itself into the already existing APA divisions, I think there might have been an earlier influence, and even marriage, with the positive psychology folks, and you wouldn't have the split that there is now. Not that the two groups are antagonistic, they are just moving in different directions.

Now when the transpersonal psychologists got the number of votes and decided to appear before the APA council they solicited advice, but my advice was not taken. I said you have to speak in the language that the council will recognize. First of all come up with an operational definition of transpersonal psychology. Secondly, ground it in mainstream psychology. William James used the word transpersonal,[8] go back to William James; everybody in psychology reveres William James. I gave a couple of other guidelines that were not taken, and the APA council voted it down, not once, not twice, but three times.

But did all my work go in vain? No, because some years later I was on the committee that came down to check into accreditation for ITP; although I cannot reveal what went on in the deliberation session where we voted to give accreditation to ITP, I used the same arguments that had been lying around for 20 years. I gave an operational definition of transpersonal psychology, grounding it in the mainstream of the psychological history, et cetera, and they said thank you for educating us about transpersonal psychology; it is not as far out as we thought it was. This is as much as I'm allowed to say, but you see the results, ITP is a flourishing institution and I'm delighted.

Still the question remains, should transpersonal psychology be a separate division of APA? Right now there are plenty of transpersonal programs at APA, most sponsored by division 32 or humanistic psychology; some by the division for the scientific study of religious issues, some by other divisions. I think there is enough transpersonal work going on, and I am really against too many divisions in APA. There are 52 right now, going on 53, and this cuts into the time that other divisions have to present their programs at APA. I am not wild about the idea of a division of transpersonal psychology in APA, frankly, because I do not think that it is needed. I think that there are vehicles for transpersonalists like me and other people to present our ideas in other divisions and then diffuse the work, spreading the word to get other people in other divisions interested. So we'll see what happens.

Schroll: Thank you Stan, so the message is to network with these other groups. I had an image while you were talking where each one of us can be an autonomous member, and yet to see the whole we have to be able to have these dialogues with other people and find a common language. In other words, what you are saying is rather than continue to work for a division of ATP in the APA, it is better to try to find a common ground of dialogue, and/or a conceptual model or a genealogy of where our roots come from in terms of our ideas with these other groups.

Krippner: Yes, that's my position; I might be wrong but that is where I'm coming from.

Vich: Could we say something about this from a slightly different perspective? When we were formulating AHP and ATP, their publications, and gathering people together at conferences to create an identity as to what we thought might be called transpersonal psychology, there was an assumption that first we had to understand what we were doing. What are we about? So that first phase was the identity development phase. There was an interesting period - I guess late 1970's early 1980's - where a concern was raised. The concern was this. If we tried to assimilate (or have too much connection with other systems or fields in whatever profession), this would risk transpersonal psychology's independence along the lines that Jim was talking about earlier concerning institutions.

The final point is about the future of educational institutions and licensing and so on. This oddly enough occurred to me very late in the game of almost 40 years of work. In a way maybe it does not make any difference what happens organizationally, politically, and so on. This is because at the root human beings are always going to have this interest, this inclination, this desire for understanding, this awareness, this questioning of where they fit into the big scheme of things, and other basic questions are always going to be there.

So those of us that are working in this field, we are working with forms, with channels, with methods, with systems, and I was able to be personally relieved of the concern that all this might pass away if we did not get approved or recognized, or licensed or whatever. Whereas the basic fundamental concerns always exist and they are rising and growing, so this is the assumption that I'm operating under. We just happened to live at a time when particular institutions are helpful necessarily and useful to people.

Schroll: So the practice of transpersonal psychology/transpersonal psychotherapy takes another form. Some people take the path - they go the ministerial route and/or pastoral-counseling route - and this is the other possible option, the spiritual psychology option. This is where people like Stan and Jim do not have to call themselves a clinician; they can call themselves a spiritual minister or some word that people can recognize so they can actually get paid for what they are doing.

Krippner: Like a spiritual coach.

Schroll: Right - so we need this language. Would people wanting to be counselors from a transpersonal perspective be opposed to calling themselves a spiritual coach? We may have to change or broaden our definition of what we mean by religion; and/or focus on developing an expanded operational definition of what it is we mean by religion.[9]

Mojeiko: I think that one problem that would arise that has in the past - or at least as far as from the perspective I'm most knowledgeable about - which is issues concerning the psychedelic therapist. Once the study of psychedelic therapy or psychedelic counseling is in a medical model it is more accepted, it is more reviewed, there are more people that are watching out and making sure that what the person is doing is ethical. As people go more and more underground there is more of a chance the kind of therapy that they are offering people is not actually helpful. It might be more harmful, and this is something to think about when there is no real law or rules overseeing its operation. Regarding psychedelic therapists in particular, one thing that MAPS [or the Multidisciplinary Association for Psychedelic Studies] is starting to develop is some kind of training program and accreditation for people that are doing psychedelic therapy; because there are a lot of particular issues that come up.

There has traditionally been a lot of sexual abuse between therapist and client; this is just something to think about. I have heard so many reports - there are a lot of clinics that people can go to where they can take ayahuasca in South America, and - except for MAPS - there is not any larger organization reporting on which ones are ethical or safe. We have so many people calling our office, because it is really the only group of people to call about such a thing, just complaining that certain groups and/or individuals are dangerous; or are not what they advertise themselves to be. I guess either way it would be good to have some kind of licensing board - yet order and rules are not typically my thing. Still I can see some benefit in having some kind of structure, whether it is medical or religious.

Schroll: You mentioned ethics, or more specifically an ethic of behavior, this reminds me of all of the problems with gurus and the tendency of the so-called spiritual teacher to abuse their power and authority, and likewise various problems with sexual issues or any issue. Because having sex should certainly be consensual, not about power and control, and this is where we need some kind of an ethic that involves regulating behavior.

Mojeiko: But whose ethic? Where does it come from?

Schroll: From my perspective, it comes from talking, from getting feedback from other people, and by working it out through dialogue with others - just like we are doing right now - as a community.

Fadiman: If you kind of look at history now and then, you find experiments that have been tried. In the USA up until about 1830 there were no licensing laws about any kind of medical practice, psychological practice, spiritual practice, et cetera. The rule was that any practitioner or anyone that called themself [a practitioner of medical, healing, spiritual arts] could charge you and if you felt that you had been harmed, you could sue; that was it. Eventually, however, the American Medical Association was formed, and not with the concern of creating the kind of high minded ethical rules that we hear from you - [Mark and Valerie], because the AMA's creation did not in any way deal with psychedelic experience.

Instead, the founders of the AMA were aware there was a competitive medical form called homeopathy. And they established rules which if you did not know what the game was, said that you [- as a practitioner of medical, healing, spiritual arts -] should have a certain amount of laboratory equipment - microscopes, slide trays, etc. - all things that homeopaths did not need. Then the AMA turned around and said, now let us accredit each other and surprise, all of the homeopathic schools were not accredited. The question is has medicine in the USA [established itself and become a] beacon throughout the world of how it should be done? The answer is in certain areas yes, absolutely, and in other areas [not at all, but] is simply a method of keeping ways of healing out of peoples hands, [and this] is a problem.[10]

The issue gets more interesting when we ask, is there [or would there] be any motive for accreditation other than good? The answer is that in most human institutions there are people that sometimes have a different point of view. I love the idea that MAPS wants to be in the training business; but I am not sure that MAPS wants to be in the accreditation business.

One of the things I like about the church and state issue is you can really be a wacko religion, and there is an enormous effort not to stop you. Let me give you an example of where this issue comes up tough against the culture. Now this is not a wacko religion. This happens to be (I think it was a Vietnamese or Hmong group) that came to the USA after what we did to their countries, and among the things that they would do in the park in San Francisco is catch squirrels and eat them. This was part of their religious practice, and you could just see the cultural discomfort of people saying, Well you cannot just kill these little animals. But it is their religion. But they are killing squirrels! Had they eaten rats, or pigeons, it might have been a different issue.

Consequently when you watch people trying to protect you from something it is well worth looking at what are the underlying cultural assumptions. One of the ways the use of ayahuasca passed the Supreme Court was based on the concern about whether or not they wanted to start legislating which religious practices are acceptable. Also, ayahuasca has one very beneficial side effect that helped its case, which is people that take it almost always have nausea and vomiting. The Supreme Court said yes...

Laughter from the gallery.

Fadiman: this is probably not going to become a recreational church. This genuinely helped; again, what is an acceptable or unacceptable practice, just as in our personal life where do we want licensing to protect us and where do we want freedom to make an informed decision? There are no right answers; but watching the way this process moves through history sometimes is helpful.

Schroll: This might be a good place to raise the issue whether people should just chose to empower themselves to try to develop an alternative position or practice and then hope that people will come to them and pay them money for their services rather than worrying about accreditation. Likewise rather than worrying about getting a division of transpersonal psychology in the APA, therapists should empower themselves by saying if you believe in what we are doing, and it seems right for you, and you think I am helping you, would you pay me? Or you can just go somewhere else for whatever kind of help you are seeking.

Fadiman: It's an alternative model, it's called education. How do we deal with education? If it is good, we pay for it. If it is not, we do not pay for it. Are there bad schools? Are there schools of the dark side? I think so, but they are mainly APA approved, so I cannot say much.

The Challenge: Defining Transpersonal Education

Fadiman: Are there schools that go out of business? Are there schools that thrive? Are there schools that break whatever laws there are? We can say yes to all of these. Now I being a crank, long in the tradition of crankdom, I think that psychology made a terrible mistake when it looked around the university when it was just a little child and it saw who the big kids were that received lots of money. It was not the French literature department, and it was not even sociology; it was hard science that received funding. So psychology said, we are a hard science; the academy said, you are kidding. No, we use numbers. Where? [This of course raises the issue of methodology, which continues to be a matter of concern within humanistic and transpersonal circles (Schroll, in press).] The helping of another human being by talking with them became - partly because Freud (who made this discovery) was a practicing physician - allied with the medical model, and I'm not sure this was a good decision.

It could have become allied with the educational model. Have you ever been to a wise being, and then did you ask what their credentials are? For example, you say that you are a Hindu sage; how do I know that you have the right credentials to be a Hindu sage? The wise being replies, that is a very interesting question that you should ask. In my seven lifetimes ago I did have a degree. Now what is your real question? The point is, it is a different model, and there are different models and fortunately in a culture that allows for different models we do not have to choose one or the other.

Now I'm coming from both not being licensed in anything I have ever done and being a minister - in case someone dies or wants a wedding. But I cannot say the theology is very deep in my church, since it is the same as one of Stan Krippner's churches. The point we are raising here is what is the purpose of what we are doing, and what is the best way to achieve it? I listened to a presentation this morning, about a model of working with psychedelics. The core of the model was, does this way of working increase suffering or decrease suffering? This was the core question around which everything else arises quite naturally. This too is another way of framing what we are talking about regarding accreditation and licensing.

I would by the way not want to leave off ecopsychology, which probably is the least appreciated and most failed system we have. We are now all aware that if there is anything that we had to guess is the major problem the world is suffering from, it is that civilization as we know it may simply melt, fry, boil, hurricane, storm, drought, itself out. Now who should be consulted at the highest levels of government in the world? Ecopsychologists. Is it happening? Not yet, do you have anything to say about this Mark?

Humanistic and Transpersonal Vistas: Ecopsychology's Role in Shaping Our Future

Schroll: I think this is where we get into this problem again: where does ecopsychology fit in? Is it within ATP and ITP; because certainly we are bringing it up here and I have brought it up at past ATP and ITP meetings, but I do not think that ecopsychology is a field. This is not just me talking, but the echo of a point Ralph Metzner and Theodore Roszak came to agree on at the 25th Anniversary Convocation of the Association for Transpersonal Psychology, a view that is shared by Robert Greenway.[11] I agree ecopsychology is not a field, it is an emerging conversation that is happening, or should be happening, in every discipline; it is also not just a conversation we need to be having in science, but it should also be part of the humanities central core. Indeed everyone should be involved and engaged in trying to keep us from cutting ourselves off from the living systems that we are a part of.

Krippner: I'd like to underline what Jim just said, that this is a real opportunity for transpersonal psychology. Remember I said earlier that Maslow was hoping to move into a trans-human psychology, which in his conversations with me I would interpret as being ecopsychology; and nobody else is doing it in terms of major organizations. I think that ecopsychology is absolutely critical. I've written some articles in which I've said that if we are stuck with the *Diagnostic and Statistic Manual*, and if this is something that is going to chart the course of psychopathology, we should have a category for people that are destroying the environment. Persons that are doing this should be diagnosed as pathological and they need help, because they are doing something that is increasing human suffering and the suffering of all sentient beings.

A few years ago I received an award from APA, so I had an opportunity to publish an article in the *American Psychologist*. In my last section I put in a plug for ecopsychology - which is the only time that I know of that it has been mentioned in the *American Psychologist* (Krippner, 2002). I did not have very many words, but I wanted to make sure that I was heard loud and clear on this issue. The way our planet is being devastated, and how the groups with the power and money are abetting and not holding back on this devastation is clearly pathological. If you saw the documentary *The Corporation*, you know that the Corporation was diagnosed as what we call a sociopathic personality. One aspect of this pathology that this film failed to mention is the devastation of the environment that most corporations - not all - are up to.

The ironic thing is that some very conservative Christian church organizations are becoming green. They are coming out for stewardship of nature, they are not coming from the same place where I am coming from in terms of my theology, but at least they are ending up in the same place. So there are some hopeful signs and I see this as being a transpersonal vision. But I have to say that with the exception of indigenous people like the Native Americans, the major religions in the world have dropped the ball on ecopsychology - both Eastern and Western. Now it is time to pick up that ball and get rolling with it before it is too late. [Indeed] any of us that have been reading or seeing documentaries on this topic know the critical situation that the world is in. And I think, Jim, that if psychology - instead of aligning itself with the physical sciences, had aligned itself with philosophy, we would not be in the mess we are in now. Because from a philosophical point of view we would have realized some of the issues that psychology, from a hard science point of view, has ignored until now.

Fadiman: William James who created psychology, eventually - and is best known - for ending up in philosophy, where he could deal with more problems seriously. To the extent that we honor, venerate, and celebrate him, we would probably do well to read him. Both because it will embarrass us how well he writes, and because the issues he raises are the issues that we are raising. Some of which will be commented on by me later in my presentation this afternoon.

Vich: I wanted to add something on the ecopsychology issue, it is not something that I have done much development in, but two things. One is the film *An Inconvenient Truth* by Al Gore, which I gather a lot of people have seen - how many of you have seen it? A lot of you it seems. This is really quite a cold shower for anybody that for the first time has encountered the concerns of how precarious our current situation is relative to the issue of global warming.

At the end of the film, Gore is on this elevated ladder, plotting one of those fatal curves that goes right though the roof. He comes down and turns back to the audience and says some people when they see this - and what I've been saying - fall into despair. Gore says, I understand this. But we do not need to. Then he goes on to show these slivers of adjustment and it is like a fan, 10% if we do this, 15% if we do this, and gradually bringing that curve down. What I noticed is these slivers of adjustment are all do-ables, probably within a generation. These are things that we have all heard about, like car mileage, and power plant emissions, et cetera, and the curve starts to decline once we begin addressing these problems. These are not huge turn-arounds that can evoke cultural and economic disaster; instead these are adjustments that can be made. So the message Gore is giving us is that we have the capacity and the power to solve the problem that we have created. But you have to think large and you have to think responsible and you have to make all of these connections we have been making.

The second point goes back to the organizational question. A couple of years before I retired as editor of *JTP* at the end of 1999, I was very impressed by the British group and the British Psychological Society taking on the transpersonal issue. Especially two of its principle authors, David Fontana and Ingrid Slack (1996), who led the appeal to the British Psychological Society (our equivalent of the APA) for a division of transpersonal interest. And they got the votes 1,623 to 899 in favor, so the British Psychological Society has what they call a section of transpersonal psychology. How did they do this? What makes their situation so different? They had a list of rational arguments that were well delivered with their typical British understatement, and beautifully articulated, but the key thing I saw there that really made me feel that this was the way to do it, was they said, and I'm paraphrasing, what we are concerned with in transpersonal psychology is those very things that have created, affected, and sometimes destroyed, and sometimes improved civilizations all through time. The arts, the literature, these have all had to deal with transpersonal issues. It has affected our lives individually and personally, and in groups and collectives and entire nations and cultures. Shouldn't we know something about it?

Fadiman: (chuckling) That's just wonderful.

Krippner: Yes, that's just great. People in this group certainly know the difference between religion and spirituality; this is an important distinction, more important as the years go on, especially on this ecology issue. You're probably familiar with the United Nations quality of life scale, and when this is applied to the nations of the world, the top 10 nations that have the best quality of life, that includes the environmental aspects of culture, the top 10 nations are the nations with the highest percentage of atheists. Now we are not talking about here of forced atheism, like North Korea. We are talking about voluntary atheism. Sweden, Norway, Denmark, the Netherlands, all the usual suspects, they have the highest quality of life and the highest percentage of atheists.

What about the countries with the minimal numbers of atheists, and the lowest quality of life, and the most devastating environmental conditions, who are these? Take the top 25 countries that have the highest quality of life. Only two countries have a minority of atheists, Ireland and the USA; again this is the top 25, not the top 10. In January I was the token transpersonalist at a major conference of self-professed skeptics in Las Vegas, Nevada, organized by the Amazing Randi. It was called the Amazing Randi's Amazing conference. It was a three-day affair, and they did a poll, 85% of the people in the audience raised their hand that they were atheists. It was a fascinating conference, with Nobel Prize winners and 800 people in attendance, the largest collection of skeptics under one roof. The one theme that came up time and time again was the environment. I have not heard so much discussion of environmental issues in a transpersonal meeting, in a spiritual meeting, in a religious meeting; these folks are really on to something. They really care about the environment.

It is therefore time for transpersonal psychology, and transpersonal studies in general, to reassess and reclaim its history regarding ecopsychology so it can step forward and fill this void. I have to say that the psychedelic movement caught on to this long ago. I remember back in the 1960s, when people began doing informal work with psychedelics. One theme that came up time and time again was we are destroying the environment, and that taking psychedelics increased not only our appreciation of nature, but all forms of life. I think too the psychedelic movement has been given short shrift by historians in a number of other ways, because it also helped stimulate interest in the Peace Movement, the Civil Rights movement, et cetera.[12] Of course the psychological experimentation had its dark side - and Jim and I are very aware of the casualties of the dark side - it did have a bright side in terms of the environmental movement. We can make the case that a lot of the environmental movement's roots are in the psychedelic work that was being done informally back in those days.

Schroll: This picks up on both of these points that have been made. Miles mentioned Gore's film, saying that all of the adjustments Gore suggests are do-ables; this brings me back to what Stan was just saying about Positive Psychology being a growing movement. We need positive motivational messages in ecopsychology to have people want to become part of it. The messages from mainstream environmentalism are all negative and I have summed them up as follows.

1. The first can be referred to as *the fear approach or the rhetoric of catastrophe*.
2. The second as *the guilt approach or the rhetoric of shame*. And
3. The third as *the self-sacrificing/voluntary simplicity approach* or *the rhetoric of redemption*.

The rhetoric of catastrophe represents prophecys of doom, such as global warming, ozone depletion, deforestation, loss of species, et cetera. *The rhetoric of shame* says that the industrial nations of the world are consuming the majority of the earth's fossil fuels: coal, natural gas, and petroleum. *The rhetoric of redemption* tells us to drive less, slow down when we do drive and car pool; to turn our thermostat down, reduce human population growth, recycle, et cetera. All of these are negative in terms of their motivational message. We therefore need to re-examine motivational psychology, because we need to develop a positive motivational imagery and language to empower people to want to become part of this movement.

Fadiman: There is a curious unattractive parallel, which is it is very hard to train people to kill other people. We are really hard wired not to kill other people, yet we've managed to do a pretty amazing job of doing this. Perhaps if we looked at what could make it easier for people to become environmentally sensitive, which is a far more natural state, we might create this positive motivational imagery and language that you just mentioned, Mark. This is really what Stan is saying. I love the idea that environmental degradation should be listed as a DSM classification - it is like these horror movies where you keep getting a larger number and things are getting worse - people that trash the environment have a pathology. Imagine if the pharmacology industry got interested. I took EarthPill and I went around and all I could do was plant flowers. I feel so much better. I'm going to talk to my big farm Mafia friends. What is our time?

Final Comments and Questions

Schroll: We have five minutes left. I know all of you have dozens of questions, but we only have time for a couple. But first I want to say this is a continuing conversation. We do not want it to end today. We want this to continue to grow, not only in your own work, but also in creating future forums like this.

Audience question: I'm familiar with all of the psychedelics that were around in the 1960s and 1970s, but I've been out of that group for about 30-years now, would someone please tell me what ayahuasca is like? It must be pretty good if people are willing to risk all of the vomiting.

Krippner: It is very strong, and I do not advise that people take it outside of a church setting. If you are interested, seek out one of the Brazilian churches, and there are some operating in the USA and Western Europe. But it is very powerful. I have learned a lot from it. I am one of the very few people that have not thrown up. This does not mean that I will not vomit the next time, but maybe I am hopeless. If you vomit this means you cleanse yourself of all your impurities. Maybe I'm too far gone to get rid of them all. But do not let this phase you, because once you vomit, I'm told that you feel beatific for the rest of the experience. Again, I cannot recommend it because it is so powerful, but if this is your personal choice and if you are invited to a church session, then you might consider it. But be prepared as to what you want to learn from it. Ask yourself, what do I want to get from this experience, which will help you operate within a framework. And be prepared to follow the rituals of the church, because they are for your own benefit very stringent, very regimented, and do not allow much of a chance for you to go off and do your own thing. You have to stay within the structure of the church.

Fadiman: This is what we used to call the three variables, drug, set, and setting.

Krippner: Yes.

Fadiman: And in this case they are welded together, as Stan said, so keep this in mind.

Mojeiko: I think too that while it might be helpful for a person doing a particular therapy to keep drug taking a secret, in general it is not a good idea. For the average person that has taken psychedelics, it is not a really big risk to say that you have done them. And it is not going to become more acceptable unless people stand up and speak out about it, so I think that maybe this is what we still need to deal with and come to terms with as we try to integrate psychedelic experience with the rest of psychology. It is therefore worth the minute risk of coming out as someone that has used a psychedelic.

Fadiman: You see we are a lot less special than people would like to think. Remember when Stan Grof asked people this morning, how many of you have had an incredible experience, and almost everyone raised their hand; and that when Grof goes and talks to regular audiences it is also a pretty high percentage. I put out a novel a few years ago titled *The Other Side of Haight*, and everywhere I went no matter who I was talking to, I brought up the fact that I'd written this novel and that they could buy it. I would ask the damnest people to comment on what they thought about psychedelics; such as I'm sitting on a plane and there is this person that looks like he is a CIA operative and I say, I've written this novel have you ever used psychedelics? You'd be surprised how many people will say, Oh yeah in college once. I did mushrooms. Then I'd find out that they were a CIA agent or someone that worked for a pharmaceutical company that I did not like very much, and that they did not like about themselves after we had finished talking. But what I found out is that sharing something that works for you is really not a bad thing to do in almost any sub-culture, and you will be surprised at how many people respond favorably. And yes to answer your question, set and setting is a lot harder when the thing you are doing is illegal. As the early Christians used to say, I hate meeting in the slimy sewers of Rome, but this is the only place we can rent to meet. And it is important that we keep meeting, so we do what we can.

Schroll: On that note, this is a good place to end because that's right Jim. What you and Valerie just mentioned is the idea of *self-disclosure* and this is what Sidney Jourard was talking about in the earliest days of this movement, thereby linking our discussion right back to the very beginnings of humanistic and transpersonal psychology (Jourard, 1971, 1972).

Notes

1. The reference to "transpersonal science" in the title is not specifically discussed in this paper because it refers to a process of inquiry, and not a reified object of investigation. Indeed this entire conversation forum serves as one means of representing an orientation toward knowing that embodies the meaning of transpersonal science. Carl Rogers (1989) sought to articulate this means of inquiry as the need for a more human science, saying that:

   > "It appears that if I wish to become a scientist, the first step is to immerse myself in the phenomena of the particular field in which I have developed an interest. The more complete the immersion, the longer it lasts, the more I love and prize the whole field, the more open I am to all the subtleties of my experiencing, [and] the more likely I am to discover new knowledge. This means a tolerance for ambiguity and contradiction, a resistance to the need for closure, the valuing of unbridled curiosity. It means soaking up experience like a sponge, so that it is taken in in all its complexity, with my total organism freely participating in the experiencing of the phenomena; not simply my conscious mind" (Rogers, 1989, p. 269).

   Contemplating and building on the wisdom of Rogers, those of us seeking a new spirit of science beyond the restrictive borders that the modern mind is willing to explore have extended this inquiry into the farther reaches of human nature. Deciding it is time to move away from the worldview that has kept the field of psychology in a polemical dither for well over a century; a worldview that perceives any state of consciousness, which is not within the normal range of consciousness as abnormal. To accomplish this task the Association for Transpersonal Psychology (ATP) has made a unique demand, that transpersonal psychologists become practitioners of psychological, contemplative, or energy disciplines which provide direct experiential access to transpersonal states of consciousness. I have continued to elaborate on this perspective of transpersonal science as a means of inquiry in (Schroll, in press).
2. Prior to this forum during lunch, I spoke with Sharon G. Mijares about a group of therapists at The Union Institute that sought to create an alternative licensing board; she asked me if I knew anything about this. I did not, pointing out even though I was a Union Institute graduate, I had not chosen to be a clinical psychologist. Following this forum a woman introduced herself as Colette Fleur. She handed me a piece of paper that contained detailed information "for an update on the group that came out of The Union Institute to propose another accreditation process and [review] body." This group is called the Council of Humanistic and Transpersonal Psychology. Its goal is to provide organization for organizations: humanistic, transpersonal, existential, phenomenological, ecopsychological, somatic, and so forth. Contact information: http://www.chtpsy.org
3. It is not just APA controlling more and more state legislatures' licensing rules, it is also "the managed care revolution." Victoria Kuhl (1994) argued, "the circumstances that have combined to create the managed care juggernaut may render the practice of humanistic treatment approaches untenable" (p. 63).
4. On the drive from Saybrook Graduate School in San Francisco to the conference at Unity Church in Palo Alto, I spoke with Daniel Deslauriers about the process of getting the clinical psychology program at California Institute of Integral Studies (CIIS) accredited by the APA. Daniel said what is happening at

CIIS is that, on the one hand, APA accreditation is developing quite successfully; yet on the other hand, students and faculty in the clinical program are becoming isolated from the rest of the school. This is because the philosophical differences between models of clinical practice deemed acceptable to the APA do not reflect the humanistic and transpersonal views of what a healthy personality is. The frontier of clinical psychology is to continue working for APA accreditation, while at the same time develop a conceptual framework and language that is able to include humanistic and transpersonal concerns.

5. For those of us unfamiliar with the term *ayahuasca*, it is a vision-producing tea that has been used for centuries by indigenous Amazonian Indians as a sacrament. Several syncretic religious movements in Brazil that combine aspects of "Catholicism, esoteric European traditions, and Afro-Brazilian and Amazonian religion" are currently using ayahuasca as their sacrament (Horgan, 2003, p. 148). But it cannot be stressed enough that *ayahuasca is not a recreational drug*. It should never be ingested "carelessly, or without a full understanding of how it works in the body" warned botanist Jim DeKorne (p. 196). A thoroughly researched examination of ayahuasca - its scientific investigation and many personal experiential accounts - is the edited book by Ralph Metzner (1999a), *Ayahuasca: Human Consciousness and the Spirits of Nature.*
6. Richard Boire has pointed out that "The UDV [Uniao Do Vegetal church] decision is important, but also narrow. It allows hoasca (ayahuasca) [use] within the UDV, but not necessarily beyond those confines. The Gonzales vs O Centro Espirita Beneficente Uniao do Vegetal (2006), 546, U.S.____; 126 S. Ct. 1211; 163 L. Ed. 2d 1017; 2006 U.S. LEXIS 1815 is part of the current case citation; because it's so current it has not received a page number yet" (private communication, December 14, 2006).
7. In 2001 a special issue on positive psychology was published in the *Journal of Humanistic Psychology*, 41 (1), spearheaded by guest editor Grant Jewell Rich. It seems all of us that wish to make this world a better place are indeed positive psychologists, as Rich makes clear in his introduction:

> [Two past] ... APA Presidents Maslow and Rogers were both humanistic psychologists whose work focused on "positive" aspects of human nature. Even a behaviorist such as B. F. Skinner was fascinated by what "could be."... If the "good life" is to be studied and perhaps prescribed, then who will define it? A hundred or so academic psychologists and therapists? I hope the movement is much more inclusive. One must never forget the numerous mistakes made by small groups of well-meaning psychologists in the past: the lobotomies that promised cures but brought only numbed minds, the phrenologists quick to make a criminal out of a person with a head bump in the wrong spot, or the IQ theorists who used their weak data and lofty positions to enforce racist eugenics programs. Positive psychology is an exciting movement, but it is one that must be tempered with cautious optimism and a healthy dose of diversity. Although Tolstoy wrote a brilliant novel with the opening statement that "all happy families are alike," I have serious reservations about a positive psychology that offers a single prescription for the "good life." (Rich, 2001, pp. 11-12)

9. See Schroll, 2005b, 2005c.
10. The observations of Jeanne Achterberg (1990, 1991), who has traced medicine's evolution from pre-history to the present, echo those of Fadiman.
11. See Greenway, 1994, 1999; Metzner, 1993; Schroll, 2007, 2009a, 2009b, 2009/2010.
12. Metzner (1999b, pp. 169-170) echoed the view that psychedelics act as a catalyst that assist us in breaking free of the habits of cognition (Schroll, 2005b; see also Metzner, 2008, p. 42; Schroll & Rothenberg, 2009).

About the Authors

Mark A. Schroll, PhD, serves as Editor for The Rhine On-Line: Institute for Consciousness Studies Newsletter, www.rhine.org; he is on the Windbridge Institute Scientific Advisory Board, the Editorial Board Journal of *Ecopsychology*, the Advisory Board Alternative Therapies in Health and Medicine, and he is the 2009 Co-Chair for Bridging Nature and Human Nature, the annual Society for the Anthropology of Consciousness conference co-sponsored by the Association for Transpersonal Psychology. In addition, he is Guest Managing Editor of the special Anthropology of Consciousness issue, Bridging Nature and Human

Nature: Envisioning Transpersonal Ecosophy, which is due out spring 2011. Schroll is a transpersonal cultural theorist and conference organizer with multi-disciplinary interests ranging from philosophy of science to ecopsychology.

Stanley Krippner, PhD, is Alan Watt's professor of psychology at Saybrook Graduate School, San Francisco, is a Fellow of four APA divisions, and past-president of two divisions (30 and 32). Formerly director of Maimonides Medical Center Dream Research Laboratory, Brooklyn, NY. He is co-author of Extraordinary Dreams (SUNY, 2002), The Mythic Path, 3rd ed. (Energy Psychology Press, 2006), and Haunted by Combat: Understanding PTSD in War Veterans (Greenwood, 2007), and co-editor of Healing Tales (Puente, 2007), Healing Stories (Puente, 2007), The Psychological Impact of War on Civilians: An International Perspective (Greenwood, 2003), Varieties of Anomalous Experience: Examining the Scientific Evidence (APA, 2000), and many other books.

Miles A. Vich, MA, D.H.L., (hon). Has served in various roles, 1962-1999, in the fields of humanistic and transpersonal psychology, including staff positions with The Journal of Humanistic Psychology, and editor of JHP (1968-1970). He is founding Board member of the Transpersonal Institute, The Journal of Transpersonal Psychology, and the Association for Transpersonal Psychology. He served as Executive Director of ATP for many years and as editor of JTP from 1975-1999. Since retiring in 2000 he has consulted on various projects, pursued a longstanding interest in art, and archived many transpersonal documents in the library at the Institute of Transpersonal Psychology, Palo Alto, and many humanistic era documents in the University of California Santa Barbara Davidson Library.

James Fadiman, PhD, received his doctoral degree from Stanford University doing psychedelic research (with and without government support). As a Harvard undergraduate he worked with Ram Dass (Richard Alpert) and Timothy Leary. He is a cofounder of The Institute of Transpersonal Psychology, where he still teaches, and was the director of the Institute of Noetic Sciences. His books include Unlimit Your Life, Essential Sufism, Personality and Personal Growth, 5th ed, and The Other Side of Haight.

Valerie Mojeiko, BA, Program Director and Clinical Research Associate, has worked with MAPS - the Multidisciplinary Association for Psychedelic Studies since 2000, facilitating research of the healing potentials of MDMA (Ecstasy), LSD, Ibogaine and other psychedelic medicines. In her work leading MAPS' psychedelic harm-reduction project, Valerie has prepared over 2000 volunteers to provide peer-based psychedelic emergency services from Burning Man to Tel Aviv. Formerly educated at New College of Florida and the California Institute of Integral Studies (CIIS).

Abstract

Shamanism and psychedelics are central to understanding the evolutionary roots of ecopsychology and its basic principles. The ancient ritual roots of shamanism constituted the context within which psychedelic experiences contributed selective influences to the evolution of human neuropsychology. Both shamanic psychology and ecopsychology involve a neuroepistemology that reflects the neurotransmitter effects of psychedelics on cognition. Shamanism contributed to the development of our ecopsychology through influences on psychological, social and cognitive evolution. Shamanism embodies the concept of animism, the notion of the spiritual essence of all nature which is recognized as the core of the oldest of humanity's religious beliefs. Shamanism provided the context within which this animistic attitude and the sense of the sentience of the many entities of the world were developed, especially in the relationship to animals. Animal species and their variant qualities provided a natural metaphoric system to structure psychological development and the evolution of social organization. Within the context of shamanism, the worlds of animal species and spirits intertwined in the creation of symbolic potentials for the differentiation of self - embodied in animal spirit powers - and the collective identity of society - embodied in totemic animals. This incorporation of the elements of nature into personal powers and social identity made shamanic ecopsychology a basic feature of human nature and culture.

Keywords: shaman, ecopsychology, animism, psychedelic, evolution, totemism

Introduction

The natural or evolved psychology of human consciousness, including its natural and social ecopsychology - is founded on principles intrinsic to shamanism. Shamanic ideology, psychology and manifestations of consciousness are based in biological structuring of humanity's evolved psychology and its consciousness of nature. Key biological contributions to both shamanic psychology and ecopsychology are the effects of substances called psychedelics, hallucinogens, entheogens, and other terms, including psychointegrators (Winkelman, 2007). These substances have key effects on the world view and principles of shamanic consciousness and ecopsychology because their effects on neural transmission produce a neuroepistemology and worldview that reflects neurophenomenological principles related to integration, connection, identity and unity with nature.

The ancient ritual capacities of the hominids, the common ancestors of humans and the great apes, share commonalities that provide a baseline from which we can infer and assess the evolution of the ritual practices of hominins (our uniquely human lineage) (Winkelman, 2009, 2010c). These commonalities reveal the ancient ritual roots of shamanism and the social context within which psychedelic experiences contributed selective influences to the evolution of human ecopsychology. Evidence for their influences on human evolution is found in the greater sensitivity of psychedelics for bonding with the human serotonergic system than is the case of other hominids (Pregenzer *et al*, 2007). This indicates that advantages conferred by the ability to benefit from these experiences were selective forces shaping the evolution of uniquely human cognitive capacities. The effects exerted by psychedelics on cognitive evolution are reflected in the common world view found in psychedelic traditions worldwide and their similarities to the basic ideologies of shamanism - such as the roles of plant and animal spirit powers and their healing potentials.

Shamanic ritual was a context for the development of our ecopsychology because of the fundamental contribution of shamanic neuropsychology to human relations with nature in general and human psychological, social and cognitive evolution in particular (Winkelman 2002, 2010a). Shamanism embodies the concept of animism, the notion of the spiritual essence of all nature which is recognized as the core of the oldest of humanity's religious beliefs. This ancient animistic awareness of some sentience and purpose of nature was developed in the context of a more ancient ritual core revealed in the direct similarities of shamanism with rituals of the great apes. Shamanic ritual practice, experiences and ideology were the foundations from which humanity's ancestors and early societies developed their understandings of nature and its relationship to self and other.

Shamanism provided the context within which this general expression of an animistic attitude, the sense of the sentience of the natural world, underwent a special development in relationship to animals. Animal species and their variant qualities were the natural tapestry within which human psychological development occurred and contributed to the emergence of more complex social evolution. Animal features and relations were the framework used to conceptualize our individual qualities and potentials and the collective identities that produce society. Within the context of shamanism, the world of real animal species was used as symbolic tools for the differentiation of self - embodied in animal spirit powers - and the formation of collective identities of society - embodied in totemic animals. These practices were cognitive adaptations that extended human cognitive capacities through metaphoric modeling, an extension of innate capacities for representing significant variations in nature to produce the symbolic. In this sense, a shamanic biopsychology was involved in the origins of the symbolic, producing a differentiation of human individual identities and human social collectivities which constituted the social other, the most basic reference for consciousness.

These arguments are supported in the following sections of this article which demonstrate:

- The basic nature of shamanism found in pre-modern foraging societies worldwide;
- Evidence for the antiquity of shamanism as a psychological, social and ecological adaptation derived from hominid ritual capacities;
- The role of psychedelics in human evolution and in stimulation of our ancient "animal brains";
- The rationale for a necessary relationship of shamanism to psychedelics and ecopsychology in the homologies of shamanic ideology and practices with the effects reported for psychedelics;
- A neurophenomenological model of psychedelics as producing the psychointegration that exemplifies

ecopsychological assumptions; and
- The roles of nature relations in the fundamental principles of shamanism, exemplified in animal spirit powers and totemism.

Shamanic universals and their evolutionary origins

The existence of remarkably similar spiritual healing practices world-wide was noted long before the modern comparative research of Eliade (1964) who popularized the notion of the shaman. There was a widespread recognition in comparative religion and deep in human history and prehistory of shamanism as a common spiritual heritage of humanity found in pre-modern societies worldwide. These intuitions about strikingly similar spiritual healers was supported by cross-cultural research (Winkelman, 1986, 1990, 1992) which empirically established the cross-cultural presence of shamanism in the pre-modern world by showing these common patterns of behavior and belief were virtually universal in foraging societies.

These features associated with shamanism in pre-modern societies worldwide include:

- The shaman as the preeminent social, political and spiritual leader and healer of the group.
- The shaman's nighttime charismatic performance with all of the community in attendance.
- Alterations of consciousness produced though physical austerities, fasting and sexual abstinence and ritual activities involving prolonged dancing, chanting and singing, extensive drumming, and frequently psychedelics.
- A period of physical collapse while experiencing an alteration of consciousness conceptualized as magical flight, soul flight, or in modern terms as astral projection.
- Activities of healing and of protecting from spirits and malevolent shamans focused on the recovery of lost souls, extraction of sorcery-causing objects and removal of the negative influences of spirits.
- Selection of the neophyte shaman involving premonitory illness and dreams.
- Shamanic training though a vision quest that involved prolonged periods of solitude in the wilderness.
- A formative initiatory experience involving the experience of death by animals and rebirth in which the animals reconstructed a new person, incorporating themselves into the shaman.
- Special relations with animals, including power relations with animal spirits, the ability to control animals and to transform into an animal.
- The belief the shaman can harm and kill magically.
- Special abilities, including the reputed ability to control weather, to physically fly, and to have immunity to fire.

Shamans and shamanistic healers

Two different concepts of shamanism were offered by Eliade, contributing to confusion regarding just what ought to be considered a shaman. The most general characterizations of the shaman were someone who entered into ecstatic states in order to interact with the spirits on behalf of the community. This conceptualization is true of shamans, but insufficiently specific because such practices constitute a cultural universal - all societies have practices involving the alteration of consciousness to engage spirits in rituals for healing and divination (Winkelman, 1992). In order to distinguish this broader group of spiritual healers from the shamans of hunter-gatherer societies, the term *shamanistic healers* was proposed (Winkelman, 1990, 1992) to refer those healers which share features with shamans, but which are distinguished from shamans, who have the additional features specified above. Eliade included many of these additional features of shamans, such as death and rebirth experiences, soul travel and animal familiars.

The worldwide distribution of shamanic healers in the pre-modern world establishes that shamanism is based in an innate biopsychology, a neurological foundation for an ancient natural religion. This ethnological analogy provides a shamanic paradigm, a biogenetic structuralist framework that helps to identify evidence of the central presence of shamanic activities at the origins of the Homo genus (Winkelman, 2010b) and at the dawn of culturally modern humans during the Upper/Middle Paleolithic revolution more than 40,000 years ago (Clottes & Lewis-Williams, 1998; Whitley, 2009; Winkelman, 2002).

Shamanism provided ritual technologies for integrating a variety of capacities - biological, social, and cognitive

- that contributed to human evolution, adaptation, and survival. These features included the differentiation of personal identity, the integration of social identities, the enhancement of extrapersonal cognition and production of symbolic thought (Winkelman, 2009, 2010a). Shamanism arguably constitute the most ancient of all human neurotheologies (Winkelman, 2004a), a biological structuring of perception, cognition and action that involved intimate relations with nature for understanding the qualities of humans. The origins of the underlying principles of shamanic psychology as well as ecopsychology are derived from basic aspects of the human mind and ancient adaptations to nature. Shamanism is indispensable to ecopsychology because shamanic practices and world view provided the context for the evolution of modern humans and human consciousness (Winkelman, 2010a). A wide range of shamanic features involve fundamental ecopsychological relations, such as perceptions of the sentience of nature, isolation in nature as part of shamanic development, and the roles of animals in the formation of self-concept and society. Shamanism contributed to cognitive, social and psychological evolution through symbolic exploitation of innate aspect of relations with nature. Elements of nature provided a natural metaphoric system for the extension of meaning in developing understandings of our individual qualities and the collectivities that produce society. These symbolic referents are typified in animals which express aspects of shamanic power and in tribal totems where animal species and their relations provide a conceptual system for social organization.

Nonetheless the concept of shamanism remains contentious for some, with the view that it is merely a modern creation or myth often used to discount any need for serious investigation. Empirical studies (Winkelman, 1990, 1992), however, show that there is a cross-cultural phenomenon that closely corresponds to the classic notions regarding shamanism. These cross-cultural similarities in shamanic practices provide the basis for establishing an ethnological analogy (Winkelman, 2010a & b), a shamanic paradigm derived from the empirical features associated with shamanism worldwide. These features provide a basis for inferring evidence of shamanic practices in the deep past and establishing a central role of shamanic ritual in human cognitive evolution. The inference of shamanism in the past is as reliable as inferring the presence of families, foraging lifestyles and other features of hunter-gatherers derived from analogies based on near-modern groups.

Furthermore, the basic dynamics of shamanism revealed by this cross-cultural research shares substantial similarities with the rituals of our closest extant primate cousins, the chimpanzees, pointing to a deep biological basis for shamanic rituals. Homologies of chimpanzee rituals with shamanism include features such as: the most significant community ritual, community-wide participation, night-time activities, performance by alpha male, use of drumming, presence of bipedal displays ("dance"), community integration activities, etc. (Winkelman, 2009, 2010a, 2010c). These similarities further substantiate the inference of shamanism in the human past and provide a bridge for inference regarding the nature of ritual activities over the course of human evolution.

The ritual antecedents of shamanism

The ritual capacities that Davis (1998) proposes as basic to ecopsychology have their foundations in ancient evolutionary adaptations that gave rise to shamanism. Shamanism must be considered to have a central role in humanity's ritual origins because of the evidence for the universality of shamanism in hunter-gatherer societies worldwide. This universality implies shamanism's intrinsic relation to humanity's ritual origins. Shamanic ritual and world views not only provided the most significant spiritual traditions of the foragers of the pre-modern world but also a bridge from pre-modern hominid ancestors to the ancient modern humans as well.

Animal displays, often called rituals, point to a deeply embedded ancient phylogenetic system of social communication which provided the biogenetic structural foundations of shamanic ritual (Winkelman, 2010a: Chapter 6). The biological bases and adaptive functions of shamanic rituals are illustrated by the nature of animal ritual (e.g., see Winkelman & Baker, 2008), and their homologies with human behaviors. Ritual provides the most evolved mechanisms for communication and social coordination in the animal world (d'Aquili, Laughlin & McManus, 1979; Laughlin & d'Aquili, 1974). Animal rituals use behaviors, particularly the initial steps of behavioral sequences, to signal a disposition for social behaviors, providing social communication that functions to facilitate interactions and coordination among members of a group. (For example a bird might raise its wings in response to perception of a threat, signaling a readiness to fly). Ritual behaviors make internal dispositions publicly available, providing information that helps produce socially coordinated responses.

Converging evidence indicates that shamanic rituals have deep evolutionary origins that predate the evolution of modern humans (*Homo sapiens*). The similarities in hominid rituals, revealed in the commonalities across great apes, and the homologies of these with basic aspects of shamanic rituals, attest to the latter's ancient roots in behaviors shared more widely with primates (Winkelman, 2009; 2010a: Chapter 6). The commonalities involve: the most dramatic of rituals, an inclusive community ritual dominated by aggressive alpha male displays; a focus on night-time activities; the use of drumming, including use of hands and sticks; emotional vocalizations; and bipedal displays, or "dancing". The similarities of shamanic rituals with the rituals of community integration used by the great apes illustrate the *a priori* role of shamanism in the evolution of human ecopsychology. These ancient hominid roots of shamanism were the ritual context within which psychedelic and animistic experiences were interpreted. Subsequently, the evolution of capacities for dancing, rhythm and enactment, which derive from a common mimetic core, provided the foundations for uniquely human culture (Donald, 1991). These communicative systems were expanded by the evolution of the musical capacity, as well as vocalizations involving chanting and singing, which extended the ritual core of shamanic practices derived from our hominid heritage.

Psychedelics and shamanic ecopsychology: drugs and human evolution

Central ecological influences on the evolution of shamanic consciousness involve psychedelics, also called "entheogens" - meaning that they elicit the divine within the self. These plants known by names such as the food of the gods and sacred medicines are recorded in the cosmologies of societies worldwide as inspiring the origins of culture, religion and spirituality (e.g., see Rätsch, 2005; Schultes, Hofmann & Rätsch, 1992) before becoming degraded as "hallucinogens" in the modern world. The use of psychedelics in shamanistic practices around the world illustrates these substances and their biological effects are central to understanding the nature of shamanism.

The essential role of psychedelics in humans' evolved psychology and ecopsychology is established by Prezenger et al's (2007) findings of significantly higher binding of psychedelics to human versus chimpanzee serotonergic receptor sites. This difference illustrates that selection for an enhanced capacity for use of these substances as neurotransmitter analogues was a part of human evolution. Humanity's evolved psychology must be understood in light of the specific effects caused by these substances, exemplified in the effects of psilocybin-containing mushrooms. There is a range of specific cognitive, social and emotional experiences caused by these substances, independent of expectation, which illustrates that they have an intrinsic neuropsychology and neurophenomenology which has direct implications for understanding features of ecopsychology.

The role of psilocybin-containing mushrooms in the evolution of neural capacities that are central to the perspectives of shamanism and ecopsychology reflects their ancient role as environmental mechanisms exerting a selective influence on members of our ancestral species who were able to utilize these exogenous neurotransmitter sources of neurotransmitter substances and their adaptive effects. Species containing psilocybin have been found around the world, providing an exposure to humans for millions of years. Guzmán, Allen and Gartz (1998) illustrate the worldwide distribution of indigenous (local) species of neurotropic fungi across most ecozones, not only the psilocybin-containing species, but also others used as sacraments. Adaptation to the fungi in their environment was a significant feature affecting hominid and hominin evolution. Many mushroom species have toxic effects; some are useful food sources; and still others produce mystical experiences.

The role of psychedelics in human's evolved ecopsychology has deep evolutionary roots in the relationship of our nervous system to environmental chemicals. Sullivan, Hagen, and Hammerstein (2008) provide evidence of ancient environmental exposures to these substance that stimulated human evolution in order to make use of these exogenous substances as sources of neurotransmitters analogues. The long-term evolutionary relationship between psychotropic plant substances and humans' cognitive capacities reflects selective benefits of substance use (Sullivan & Hagen, 2002). In contrast to the debilitating cognitive effects often attributed to drugs, Smith (1999) illustrates a variety of fitness consequences associated with the use of substances often disparaged as drugs. Across the diverse classes of plant drugs there are effects of enhanced vigilance, the ability to ignore pain in the interest of survival activities, increased access to mating opportunities, reduction of apprehension and stress, feelings of euphoria, increased endurance and self-confidence, enhanced sensory and mental acuity, reduction of defensiveness, and reduction of depression and self-defeating activities. Evolutionary paradigms suggest that fitness benefits accrued to our ancestors as a consequence of their ability to utilize psychoactive substances to enhance operation of neurotransmitter systems. The effects of these environmental sources of neural transmitters display hallmark features of natural adaptations (Smith & Tasnadi, 2007).

Psychedelics and shamanic phenomenology

Our very psychology as human beings was shaped by the experiences induced by the psychedelics and their intrinsically religious effects, as well as a range of other cognitive, social and personal dispositions they produced (Roberts & Winkelman, 2013). Shamanic practices in general and the healing traditions in particular were centrally shaped by these experiences and the powers released within the person by the pharmacological effects of the active ingredients of these plants. A review of literature from around the world illustrate that the effects of psychedelics, and psilocybin-containing mushrooms in particular, produce a range of experiences that are directly related to shamanism, including (Winkelman 2010; see also de Rios, 1984; Hoffman, Carl & Ruck, 2004):

- providing access to a spiritual world, the supernatural, bringing the mythical world to life;
- producing an experience of the separation of one's soul or spirit from the body and its travel to the supernatural world;
- activating powers within and outside of the person, including the sense of the presence of spirits and their incorporation into one's body;
- establishing relationships with animals, particularly carnivores;
- inducing an experience of transformation into an animal;
- provoking a death of the ego and its transformation or rebirth, providing a source of self transformation;
- providing information through visions;
- providing healing, especially through the emotional experiences and release (catharsis); and
- inducing an integration of the group and enhancement of social cohesion reflected in their use in community rituals.

The hypothesis that these psychedelic-induced experiences are intrinsic effects of these substances is supported by their objective ability to produce a variety of mystical experiences in contemporary people. Griffiths *et al*. (2006) carefully-designed double blind study showed that psilocybin induces mystical experiences and has effects on participants' attitudes, moods, and their own experience of spirituality that persisted for months. The comparison with control periods showed psilocybin produced significantly higher ratings on the scales used to assess mysticism and altered states of consciousness, including introvertive mysticism, extrovertive mysticism, internal and external unity, sacredness, intuitive knowledge, transcendence of time and space, ineffability, positive mood, and experiences of oceanic boundlessness. Psilocybin sessions had significantly higher levels of peace, harmony, joy, and intense happiness. In addition, there were persisting effects noted for the psilocybin sessions, including an enhanced positive attitude about life accompanied by a positive mood changes and positive altruistic social behaviors confirmed by third-party observers.

While the emergence of the suite of practices associated with pre-modern shamanism involved other selective influences (e.g., dancing and music, Winkelman, 2010a), psychedelics were central selective influences on the evolution of the human nervous system for the kinds of experiences directly related to ecopsychology and shamanic ideologies. The extrovertive mystical experiences typical of psychedelics embrace the connection with the external world and nature in particular, but in a different way, with the perceiver transformed in such a way that the perception of the ordinary world of plants and rocks is transfigured into a consciousness of Unity with all of nature, rather than some sense of separateness.

These experiences are principally deistic experiences, as embodied in the concept entheogen - generating experiences of the god within one's self. A core aspect of the psychedelics experience is what Hoffman, Carl and Ruck (2004) characterized as the "entheogenic epiphany… commonly described as a state where all distinctions and boundaries between the individual and the metaphysical realm dissolve into a mystical and consubstantial communion with the Divine. This ecstatic experience is interpreted as a pure and primal Consciousness, which brings the individual into direct contact with the root of being…" (p. 112). These and other common effects resulting from ingestion of the entheogens must be understood in terms of neurophenomenology (Laughlin, McManus & d'Aquili, 1992), where physiological actions on the neurological system are responsible for the phenomenological experiences.

Psychointegrators as a neurophenomenological paradigm

The psychedelics had central roles in the evolution of human cognitive capacities, particularly symbolism, abstract thought and reasoning and the religious and spiritual capacities which characterize the human species. These effects derive from the action of psychoactive plants on the serotonergic and dopaminergic nervous systems. Entheogenic substances primarily derive their effects from chemicals compounds known as indoleamines which have direct and indirect effects on the brain's neurotransmitter systems. The major classes of indoleamines are tryptamines (e.g., DMT, LSD, psilocin, and psilocybin) and phenylethylamines (e.g., mescaline, MDMA ['ecstacy'], 2C-B) and exert similar influences on serotonergic neurons (Nichols 2004; Nichols & Chemel, 2006; also see Fantegrossi, Mernane & Reissig, 2008) and produce similar experiential effects (for reviews see Passie *et al*, 2008; Hintzen & Passie, 2010). These effects on serotonion receptors are responsible for the overall changes in brain processes, which are reflected in high-voltage brain wave discharges of a slow wave frequency: typically theta, 3-6 cycles per second (cps).

These biochemically based physiological dynamics are primarily based in serotonin disinhibition and the consequent loss of its inhibitory effects on dopamine and the mesolimbic structures, enhancing the activity of lower brain structures, particularly the thalamic area that gates information ascending from the peripheral nervous system. Serotonin-like entheogens and many other substances have end-effects that alter consciousness through a common mechanism - production of high-voltage slowwave (theta) brain wave activity (Mandell, 1980; Winkelman, 2010a). While there are many additional effects found within and across species, typical effects on serotonin receptors provide the basis for a neurophenomenological paradigm of psychedelics and shamanic altered states of consciousness as involving psychointegration produced by an enhanced integration of lower brain processes into the frontal cortex (Winkelman, 2001, 2007).

The neurognostic structuring produced by psychedelics reflects macro-level effects involving both the activation and selective deactivation of the serotonin system, which has multiple regulatory roles reflected in its special characterization as neuromodulator of many neurotransmitter systems. Psychointegration is derived from both stimulating the serotonergic system, as well as inhibitory effects on serotonin transmission (through resistance to reuptake), with consequences involving disinhibition or release of the dopaminergic system (Passie *et al*, 2008; Nichols, 2004). Nichols concluded psychedelics amplify incoming stimuli, enhancing the sensitivity of the phylogenetic older brain structures and the excitability of limbic and cortical structures.

Serotonin as a modulator

Serotonin is a neurotransmitter that acts as a modulator across all levels of the brain, from the brain stem and limbic system to the frontal cortex. Serotonin has a wide range of functions in: sensory processing and perception, motor activity and behavior, hunger and feeding, thermoregulation and pain, release of growth hormones, sleep cycles, learning and memory, moods and modulating the sympathetic nervous system (see Kruk & Pycock, 1991: 122-3; Role & Kelly, 1991). Serotonin circuitry is primarily ascending, concentrated along the midline area and the raphe nuclei and projecting upward into the limbic system and frontal cortex, with widespread and diffuse influences over vast neuronal populations. Serotonin neurons innervate structures directly responsible for a range of human capabilities central to consciousness: attention, alertness, and maintenance of waking/sleep cycles; integration of emotional and motivational processes; synthesis of information from the entire brain; and visual conceptualization and representation.

Psychointegrators' primary neurophenomenological effects reflect activation of synchronized hyperactivity in serotonin circuitry across the neuraxis, the main nerve bundle linking the structural levels of the brain from the brain stem to the frontal cortex. This hyperactivity produces synchronization of theta (3-6 cps) brain waves across the levels of the brain and between the hemispheres (Mandell, 1980; see Winkelman, 2011 for review). The theta effects begin in the midbrain hippocampal region which activate serotonin circuitry in the lower levels of the brain (locus corelus and thalamus), which in turn stimulate the limbic structures and frontal cortex, especially the right hemisphere (Mandell, 1980). Mandell proposes this is the basis of the cognitive of transcendent states, increasing the ascending flow of information, improving integration of information exchange between the two hemispheres and their specialized functions in cognition and affect, producing interhemispheric coherence and fusion that results in insight. These synchronizing effects in the brain contribute neurological causes of the integrative experiences of connection and oneness produced by these substances, and the rationale for the concept of psychointegrators.

A central feature of serotonergic systemic functions includes inhibitory or repressing activity. Psychedelics' selective effects result in disinhibition of serotonergic regulation of the thalamus and limbic areas which function as "gatekeepers" in the basic filtering of information from the environment and body. Psychointegrators disinhibit the mesolimbic temporal lobe structures, reversing the habitual effect of serotonin in depressing the action of target neurons in the forebrain. Disinhibition of mesolimbic temporal lobe structures produces key features of psychointegrator-induced changes in overall brain function - high voltage synchronous discharges in the hippocampus and other temporal lobe limbic structures manifested in theta (3-6 cps) brain wave patterns. This model of psychointegration is confirmed by research (Vollenweider & Geyer, 2001) which found the principal effects of psychedelics involve the cortico-striato-thalamocortical loops which reduce the sensory gating systems of the lower brain structures, leading to a flood of information on the higher levels of the brain.

The release of the dopamine system caused by the psychointegrator's blocking of the serotonin system produces characteristic features of altered consciousness and the ecophilic attitude of shamanism (Previc, 2009). Virtually all classes of drugs effect dopamine transmission in the limbic system, as well as on serotonergic transmission (Smith & Tasnadi, 2007) and result in increases in dopaminergic activity. Effects on dopamine receptors typically produce unconditioned pleasurable responses and elicit intrinsic feelings of well-being. While high levels of dopamine lead to emotional detachment, the human dopamine system is part of our mammalian heritage, with similar effects across mammalian species in social bonding, from mother-infant attachment to broader social groups. Psychointegrator's ecophilic effects must be seen as in part resulting from activation of our basic bonding neurochemistry, core functions in the mammalian brain's emotional, social and self systems. Previc (2009) reviews evidence that dopamine is also vital for all of the key functions of advanced intelligence and cognition and linked to the brain's ability to deal with objects and events distant in space and time. This provides context independent cognition, exemplified in the capacities for mental time travel, the ability to experience and think about things other than those in the here and now. Winkelman (2010a) shows how these abilities for extrapersonal projection are key to understanding central aspects of the shamanic soul flight or out-of-body experience, which exemplifies the ability to have a context-independent consciousness of people and places far removed from the physical body.

These combined stimulatory and inhibitory serotonergic effects of psychointegrators result in the increase in information from the environment, body and memory; the enhanced experience and recall of emotions; the stimulation of basic motivations and cognitive processes; and increases in awareness and internal attention. These produce the neurophenomenological dynamic exemplified in the concept of psychointegration, reflecting the heightened integration of hierarchically-ordered brain functions. As Nichols (2004) concluded, psychedelics enhance the sensitivity of cortical processing of ancient phylogenetic brain structures.

Psychointegration as the general dynamic of alterations of consciousness

This psychointegrative model of consciousness derived from psychedelics is characteristics of shamanic alterations of consciousness in general (Winkelman, 2010a, 2011). The biological effects of the psychedelics are mimicked by a variety of other agents and behaviors, including other drugs, long-distance running, hunger, thirst, sleep loss, auditory stimuli such as drumming and chanting, sensory deprivation, dream states, meditation, and a variety of psychophysiological imbalances or sensitivities resulting from injury, trauma, disease, or hereditarily transmitted nervous system conditions (see Mandell, 1980; Winkelman, 2010a). Similar production of alterations of consciousness through disruption of the processes of the frontal cortex occurs from the effects of endurance running, dreaming, hypnosis, drug induced states, and meditation (Dietrich, 2003).

The all-night dancing of the shaman exploits another capacity which contributes to alterations of consciousness, mystical experiences and biophilia; the uniquely human capacity of endurance running (Bramble & Lieberman, 2004). Emerging a million years ago in *Homo erectus*, these capacities for running for hours to days provided a natural basis for inducing alterations of consciousness, which also has as a side effect of the induction of mystical experiences (Jones, 2005). This effect from endurance running goes beyond the widely noted "runner's high" and includes typical features of mystical experiences such as:

- positive emotions such as happiness, joy and elation;
- a sense of inner peacefulness and harmony;
- a sense of timelessness and cosmic unity; and
- a connection of oneself with nature and the Universe (Dietrich 2003)

Sands and Sands (2009) proposed that the selection for long-distance running in *Homo* subsequently selected for a form of spirituality, a "horizontal awareness" or *biophilia* that operated through existing neurobiological reward systems. The "high" associated with long distance running situated our ancestors within a dynamic environment within which they felt an intimate connection with nature. They review evidence showing that the neurochemicals released during endurance running are tied into a variety of pre-existing reward pathways, including monoamines (serotonin, dopamine, and norepinephrine), endorphins, and endocannabinoids. Thus a side effect of the acquisition of the capacity for long distance running was a variety of mystical experiences, as well as the physical basis for dance. Dance and other shamanic practices of fasting, sexual abstinence, social isolation, drumming, chanting and austerities all contribute to this altered state characterized by theta wave synchronization. These entrainments may occur at a variety of frequencies, but two predominant patterns are synchronized slow wave theta bands (3-6 cps) and the high frequency gamma oscillations (40+ cps) (see Winkelman, 2010a for primary references).

Disruption of highly-integrated aspects of neural information processing and higher cognitive functions characteristic of the frontal lobes and prefrontal cortex allows for the manifestation of other brain structures usually repressed by frontal activities. The overall brain response to many different activities that alter conscious is characterized by brain synchronization with slow wave discharges that produces overall coherence and a linkage across the evolutionary strata of the brain, integrating information from the lower brain systems into the frontal cortex. Deregulation of the prefrontal cortex allows for the emergence of aspects of identity related to our more ancient brain functions.

The effects of psychedelics and the shamanic alterations of consciousness involve stimulating the linkages across the evolutionary strata of the brain. MacLean (1990, 1993) proposed that the brain involves three anatomically distinct yet interconnected systems - the reptilian brain, paleomammalian brain, and neo-mammalian brain. These three brain systems provide the basis for behavioral, emotional, and informational functions that MacLean (1993, p. 39) called "protomentation", "emotiomentation", and "ratiomentation" respectively. Interactions across levels of the brain are mediated through non-verbal communication forms that utilize behavioral, social, affective, and presentational (visual symbolic) information. Psychointegrators elevate these communication systems of the ancient strata of the brain. In the reptilian brain they release the activity of the raphe and reticular formations and thalamic structures of the brain stem area that normally restrict information received by the higher levels of the brain. And in the paleomammalian brain they stimulate limbic system functions that provide emotional information, a sense of personal relations and bonding.

The development of the serotonergic system across phylogenetic evolution illustrates how psychedelics can have such a central role in these integrative processes. The effects of psychointegrators on the serotonergic system and dopamine relate to MacLean's model of the evolution of the brain, functioning as the most central and powerful system of integration and coordination among the three brain subsystems. In the reptilian part of the brain, serotonin functions as a regulator system within the R-complex. Serotonergic functions in the paleomammalian brain involve control over the R-complex, inhibiting limbic brain emotional functions, and distributing information through connections with the prefrontal and neocortex.

Global effects of psychointegrators on the serotonergic system enhance reptilian and paleomammalian brain activities. Psychointegrators produce systemic brain integration through liberating our ancient animal brains, imposing the reptilian brain's ritual systems of communication and the paleomammalian brain's analogical processes and material of an emotional, social, and personal nature into the self-conscious processes of the frontal cortex. Consequently our experience of connection with nature, the ecophilia associated with psychedelics, emerges as a neurophenomenological effect. These stimulations of our ancient brain systems must also been seen as central to the animistic features of psychedelics, shamanism and ecopsychology.

Nature and animal relations in shamanism: The origins of ecopsychology

The self-identifications with the broader universe, particularly personification of the sentient cosmos which is a hallmark of ecopsychology, is also a fundamental aspect of the shamanism. This cosmic identity with nature has many roots in shamanism, such as those experiences induced by entheogenic plants generally personified as gods. The out-of-body experiences associated with shamanism, psychedelics and long-distance running all reflect a capacity to dislocate personal identity from body, a capacity which likely facilitates an identity with nature, where personal identity is often relocated.

Davis (2006) notes that central aspects of ecopsychology involve a nature-oriented awareness practices which are basic tools of shamanic development, such as the vision quest alone in nature. Shamanic development focused on intensified contact with the natural world as a fundamental tool of personal growth. Novices spend months or even years isolated from community, largely alone in the wilderness, which was key for developing relations with power animals. These extraordinary experiences were provoked by prolonged and direct contact with nature, exemplified in visions of spirit beings, especially the animals.

The shaman was known for having special relations with animals and animal spirits, being able to control them and believed to personally transform into an animal to accomplish feats. Relationships with actual animals also characterized shamans. Shamans often adopted a variety of wild animals that might live with them or visit them, especially when called by the shaman for some task. This personal relationship with animals must be seen as a precursor to domestication, a complex human relationship with transformed nature.

Shamans had special relationships to hunting animals as well, particularly leading hunts and making sacrifices to the spirits of the animals killed. Shamanism's relationships to the animals included calling them to the waiting hunters, campsites and the shore. The shaman made soul journeys to the spirit world to seek the release of the animal spirits for the hunters to kill. The killing of the animal was also accompanied by sacrifices to the animal's spirits to atone for their loss, giving thanks for the sustenance that they provided for the humans.

Shamanic ritual activities relating the group to the environment reflect a deep synchronization with ecological principles. Found within many shamanic traditions is the belief that certain animals have periods of taboo in which they may not be hunted or eaten. Winkelman and Baker (2008) discuss how the practices of hunting taboos among the pre-modern Tukano in the Amazonian region of Columbia illustrate the roles of shamans in ecoregulation. The shamanic ideology dictates what animals may be hunted and when. Beliefs about the relationship between human sexual energy and the fecundity of nature also regulate hunting and reproduction. Sexual activity is restricted before hunting and rituals performed to determine the cause of unsuccessful hunting; consequently, limited availability of game animals results in sexual restrictions and reduced human reproduction. The role of the shaman in deciding to taboo certain animals plays a direct role in regulating the community's environmental relations and the well-being of the local species, limiting exploitation so that local food species will not fall below reproduction levels.

Imitation of animals in shamanism: Hunting and human evolution

Relations with animals through hunting and imitation of them played a variety of roles in the evolution of a capacity for symbolic representation through behavior. Human evolution in relationship to nature involves enhanced skills for using culture to change from being prey into being a hunter. Key elements of hunting involve adoption of behaviors of animals and eventually involved imitation and disguise. Hunting activities became conceptualized in terms of the ability to acquire power over animals, based in knowledge of its habits, behaviors, and powers. This power was likely manifested through deception and imitation, mimicking of the vocal calls of animals to attract them or to cover one's own noise. This imitative practice of hunters is another feature of shamanism, the master of the animals. This also provided a basis for representation through mimicry.

Donald (1991) proposes that a major cognitive evolution of humans involved mimesis, the ability to intentionally represent through enactment, and that among the first of human mimetic activities were ritual group dances performed with vocalizations to imitate the sounds of animals. He suggests the mimetic capability resulted in a form of body-based awareness, a physical self-consciousness that enhanced our awareness of self-in-environment. The use of bodily movements as symbolic communication embodied in mimesis made it possible to increase group coordination because it built upon one of the most basic types of animal ritual behavior - isopraxis - in which animals automatically imitate each other's behavior.

Hunting animals likely engaged and selected for the mimetic capacity because the ability to imitate would have directly enhanced hunting success through the ability to engage in deception through imitation. Imitation also played a role in teaching about hunting and animal behaviors. Imitation used for the purposes of hunting likely produced a greater sense of identification with the animal, a hallmark feature of shamanism. This enactment of the 'other as animal' likely played a role in the evolution of shamanic practices. Mime and dancing are central features of shamanic activities, for they are the basis of the ritual enactments of struggles with spirits combined with chanting, singing, and imitative vocalization. The shamanic roots of ecopsychology involve an impulse to understand the environment in human and animal terms, and conversely the self in terms of animals and their powers. Imitation of the behavior of some of the most significant features of the environment - animals - provided a template for broader representation skills.

Animism as ecopsychological identification

One of the most fundamental features of shamanism, religion, spirituality and the concept of entheogens is the notion of the spirit world. Animism refers to the notion that nature is in essence embodied with spirit entities, and encompasses the core of the oldest and most basic of humanity's religious beliefs. Shamanism has been characterized as an animistic practice, where animism constitutes a perception of nature not as inert matter but rather as a living entity. This humanized nature is exemplified in the shamanic relations with plant spirits embodied in the entheogenic practices so frequently associated with shamanism. Shamanism personified the influences experienced from these plants, exemplified in the intimate relations they maintained with these environmentally-based entities conceptualized as plant spirits. These relations with the plant spirit others were fundamental to concepts of self, other and universe that are characteristic of ecopsychology - a perception of nature as a person, intelligent, spiritual and infinite.

Bird-David (1999) portrays animism not merely as a sense of spirits within nature, but moreover as powerful presences that must be understood as super-persons. The relationships established with the animistic super persons are reciprocal, in which one both receives benefits and privileges and to whom one has obligations met through ritual. Shamanic rituals are the primary mechanism through which these relationships are recognized and reciprocity engaged with these super-persons. Shamanic performances ritually enact these persons, bringing them to life in a heightened ecstatic state that enhances relatedness not only within community, but also in relationship to the spiritual kindred of nature. These relationships give rise to a greater sense of the interconnectivity among local community, the ecosystem and the cosmos.

One of the most fundamental shamanic relations with nature is in the conceptualization of the self and its powers, typified in the concept of animal powers that constitute basic aspects of the self. Nature itself becomes our template for society in the ancient practices of totemism where animal species and their natural relations became an innate template for conceptualizations of our lineages and tribes, the building blocks that take society into transfamilial dimensions. Shamanism provided the evolved psychological context - our neuro-psycho-social structuring as sentient beings in relationship to physical nature and its powers, animals and plants. Our natural ecopsychology is inextricably tied up in our relationships with the physical world - the animistic essence of nature as a sentient, aware spiritual power, of the animals as actors that can give us power and identity and affect our well-being.

These basic relations to the animistic principles of the universe and their manifestations in animals are deeply rooted in the structure of the human psyche, a neurophenomenological system in which the common brain structures we share with other animals (i.e., the reptilian complex and paleomammalian brain) produce an awareness of self in relationship to other animals. While this postulation of spirits which is fundamental to animism has been attributed to cognition regarding anomalous psychological phenomena (i.e., dreams, spontaneous out-of-body experiences), animism is best understood in terms of the consequence of innate processing modules. Animacy is a universal human tendency because it is an adaptive feature of human cognition based in "animacy detection". Atran (2002) illustrates how animacy detection - being hyper-sensitive to the presence of an animate agent - has adaptive benefits.

The universal human tendency for animistic thinking is a consequence of the adaptive tendency to attribute human mental, personal and social qualities to the unknown and natural phenomena. This tendency to assume the presence of an agent is combined with other innate faculties for self and other representation to produce the broad range of features typically associated with concepts of spirits (Mithen, 1996; Winkelman, 2004b; Winkelman & Baker, 2008: chapter 7). The projection of humans' self qualities to the unseen, as well as nature, is an inevitable consequence of our psychological and social development; spirits are a natural epistemology involving the inevitable projection of human models of the self.

Hubbard (2002) characterized shamanic cognition as involving extension of special attributes of human consciousness to new domains, especially the natural world which is imbued with elements of meaning and intentionality derived from humans. This reflects an innate human tendency to attribute the causes of observed actions to an object's internal dispositional factors, extending the assumptions we make about humans to unknown dynamics, assuming that other things operate as do humans. The natural tendency of humans to attribute mind states, internal dispositions and rational purpose to others is unavoidably attributed to nature as well. The universality of spiritual beliefs reflects this adaptive tendency, which was expanded into population of nature with spirit beings who operated with the same features as humans.

Spirit assumptions are reinforced by humans' innate capacities for social intelligence, our ability to infer the mental states of other members of the species and to use that information as a basis to predict others' behavior. This intuitive "theory of mind" involves the attribution of mental states to others, modeling others' thoughts and behaviors through the use of one's own mental states and feelings. Such attributions are fundamental to animism and the world of spirits. Whatever qualities of cognition, personality, intentionality and other personified qualities that nature may have intrinsically, they are modeled on the perceptual templates of those same qualities that are found universally in humans and are intrinsic to our perceptions. Our self-knowledge is necessarily the template through which we experience the other in the social as well as natural world. Nature is inherently personified via human nature.

Nature as self: Animal powers and guardian spirits

Shamanism was the original context for the spiritual perceptions that Davis (1998) see as an essential component of ecopsychology, the perspective of "nature as self". This self-identification with the world and Gaia is one of the most basic metaphors which ecopsychology provides for representing the relationship between humans and nature. A prominent aspect of spirit relations in shamanism involves an engagement of self-development processes by using symbolic representations derived from nature, and animals in particular. Animal species and their variant qualities are the natural tapestry within which human psychological and social development evolved.

The personification of nature embodied in animism facilitates the reciprocal process, the naturalization of the person. The projective processes underlying animism are used to reciprocally internalize the qualities found in nature into the person. Shamanic practices involving animal allies and guardian spirits reflect aspects of self-development and self-representation that involve the capacity to incorporate other's perceptions into the self, internalizing the qualities of others into our own self-identity. Shamanistic relations with nature engage humans' capacity for personal incorporation of others, using animals as the other.

Evolutionary psychologists recognize that humans have an innate natural history module, an intrinsic ability to recognize and categorize species of animals (see Mithen, 1996). Shamanic practices engage this specialized innate capacity for organizing knowledge about animal species and recognizing "species essence". Animal species - a highly important part of nature - provide a universal analogical system for creation of meaning. This ability to recognize intrinsic features of species and to transfer this knowledge to other domains is exemplified in the shamanic animal guardian spirit powers, which involve representations of self.

Animal powers incorporated as aspects of the self are exemplified in the guardian spirit complex typical of shamanism (Swanson, 1973). This involves ritual activities, generally prolonged isolation in nature, during which the person acquires a special relationship with a specific animal species that serves as a model for self-development. This self-development is based in the incorporation of animal properties within identity and personal powers. Swanson characterized the guardian spirit complex as a form of empowerment in which adult role development and personal and social choices are guided by the qualities of animal species. Animal spirits' characteristics provide ideals that structure individual psychodynamics and model social behavior through the natural symbols provided by animal attributes. These animals qualities provide diverse self-representations, different acquired selves that can mediate hierarchies of personal and social goals.

Animal spirits provide natural symbolic systems derived from relations with nature that serve vital functions in self and social representation within which the self is internally differentiated and socialized in relationships to others. These aspects of shamanism reflect an intrinsic neurophenomenological ecopsychology. Animal species and their qualities and behaviors provide a natural template for differentiating self with respect to others. Animal species identities provide psychosocial functions in visual icons, making publically available forms of social self-representation that facilitate personal differentiation.

Totemism: Nature relations and group identity

Shamanism exemplifies the symbolic application of nature to group relations in the practice of totemism. These group-oriented religious practices use animal species for social representations, as manifested in ancestor worship where group deities are represented by an animal species referred to in anthropology as a totem. Totemism involves establishing a metaphoric relationship between the natural history domains of animals and domain of social groups, conceptualizing humans's social organization through models provided by the animal world.

This view of totemism derives from the work of French research Emile Durkheim, the father of sociology, and Claude Levi-Strauss, an anthropologist. Durkheim (1915) investigated the widespread practices in which an animal species was used to represent a clan, a descent-based kinship group. Central worship activities of the clan consisted in ceremonies aimed at promoting the growth and well-being of the totem. During these rites for enhancing the fecundity of the totem, normal prohibitions on the consumption of the totem are suspended. During the ritual the totem animal is ceremonially killed and consumed in a sacred meal that allows the individual to incorporate the power of the totem.

While noting a variety of different phenomena called "totemism", Levi-Strauss (1962) identified commonalities underlying the many different systems and beliefs in which human clans are associated with specific animal species. In totemism, humans are identified with an animal (or plant) species unique to their kinship groups. This animal identification, a "connection between *the relation of man to nature* and the *characterization of social group* … postulates a homology … between differential features existing, on the one hand, between species x and y, and on the other, between clan *a* and *b*" (Levi-Strauss, 1962: 13). Levi-Strauss characterized totemic thought as involving analogical processes, establishing a homology between animal species and human groups. Animal species represent the distinctive qualities and membership of different social groups, constituting natural symbols for representing less distinctly featured human groups. The group identity animal species identifies the clan, and by extension, its members.

Totemism and guardian spirit relations exemplify innate nature relations that function to distinguish among humans and their groups through the attribution of characteristics derived from the natural world. Personal and group identity and intergroup differences are conceptualized through models provided by animal species. Totemism is a natural product of human thought, reflecting concepts of the natural world that are structured by the human brain, the innate intelligence for classifying the natural world. Our deeply rooted capacity to classify the animal world makes it a natural metaphoric system that can be extended to many other domains of human thought. The use of animals in social and cognitive modeling is one of the most fundamental aspects of metaphoric and analogical thought (Friedrich, 1991), a universal human system for expression of meaning and creation of social and personal identity through the use of the innate module for animal species categorization. The less perceptible differences among humans and groups are made visible with the representations derived from the more apparent differences in animal species.

Conclusions

Common features of shamanism, psychedelic metaphysics and ecopsychology illustrate that they involve common origins. Their commonalities point to a biologically based ecopsychology, one that is the product of human evolution and evolutionary adaptations. These biological bases suggest that shamanic ecopsychology and psychedelic therapies still have relevance for humans today. Our very health and survival as a species may depend on our ability to re-establish these relations with nature.

Abstract

In a large-scale (N = 1487) general population online study, we investigated the relationship between past experience with classic psychedelic substances (e.g. LSD, psilocybin, mescaline), nature relatedness, and ecological behavior (e.g. saving water, recycling). Using structural equation modeling we found that experience with classic psychedelics uniquely predicted self-reported engagement in pro-environmental behaviors, and that this relationship was statistically explained by people's degree of self-identification with nature. Our model controlled for experiences with other classes of psychoactive substances (cannabis, dissociatives, empathogens, popular legal drugs) as well as common personality traits that usually predict drug consumption and/or nature relatedness (openness to experience, conscientiousness, conservatism). Although correlational in nature, results suggest that lifetime experience with psychedelics in particular may indeed contribute to people's pro-environmental behavior by changing their self-construal in terms of an incorporation of the natural world, regardless of core personality traits or general propensity to consume mind-altering substances. Thereby, the present research adds to the contemporary literature on the beneficial effects of psychedelic substance use on mental wellbeing, hinting at a novel area for future research investigating their potentially positive effects on a societal level. Limitations of the present research and future directions are discussed.

Keywords Psychedelics, nature relatedness, pro-environmental behavior, ecology

Although clinical research conducted in the 1950s and 1960s hinted at the vast therapeutic potential of psychedelic (i.e. "mindmanifesting") substances, regulatory restrictions resulting from a combination of political pragmatism and sensationalized media coverage brought research on their effects on the human mind to an abrupt and unfortunate halt (Nutt *et al.*, 2013). In 1971, most classic psychedelics (i.e. LSD, mescaline, psilocybin, etc.) were classified as Schedule 1 substances by the UN Convention on Psychotropic Substances, creating administrative hindrances and disproportionate costs for academic institutions that made human trials effectively impossible (Nutt *et al.*, 2013). Despite the fact that experts consider psychedelics to be among the least harmful and least addictive recreationally used substances (Nutt *et al.*, 2013), research was for the most part confined to neuroscientific investigations into their effects on rodents, leaving the therapeutic potential they revealed - for example in treatment of alcohol dependency disorder (e.g. Smith, 1958) - largely untapped. As a result, research on the intricate effects of psychedelic substances on human cognition and behavior is still in its infancy. This shortcoming comes as a surprise, considering that - despite their illegal status - about 14% of all adults in the United States report to have had at least some experience with psychedelic drugs (Johansen and Krebs, 2015). Moreover, indigenous peoples have sacramentally used hallucinogenic plants for more than 5000 years, predating all major contemporary religious belief systems. How these experiences affect individuals in the short and long term, however, is not yet entirely understood, and remains an important question to attend to.

Following a gradual political shift, the last two decades saw a resurgence of psychedelic research, culminating in the first experimental study involving LSD administration in 40 years (Gasser *et al.*, 2014). First and foremost, many of these new research programs focus on clinical applications of psychedelic substances in the treatment of anxiety and mood disorders. Although oftentimes limited to small sample sizes, preliminary results of these studies indicate that administration of psychedelics can considerably benefit psychotherapeutic interventions, revealing marked reduction of anxiety in patients who suffer from various life-threatening conditions (Gasser *et al.*, 2014), as well as reduction of depressive symptoms and anhedonia in patients with treatment-resistant depression (e.g. Carhart-Harris *et al.*, 2016). A different line of research investigated the potential of psychedelics in aiding the treatment of addiction and dependence disorders. While the rarely used psychedelic compound ibogaine was found to effectively attenuate addiction and withdrawal symptoms in opiate and cocaine addicts, other psychedelics revealed broad anti-addictive qualities in the treatment of various dependence disorders, having positive effects on patients' self-efficacy and motivation to change (Bogenschutz and Pommy, 2012; Sessa and Johnson, 2015, for a review). In fact, a recent meta-analysis by Krebs and Johansen (2012) confirmed a substantial positive effect of LSD in the treatment of alcohol dependence, comprising a total sample of 536 participants.

Psychedelics' mechanism of action

The reasons for why psychedelics, most of which act as serotonin 2A (5-HT_{2A}) receptor agonists (Vollenweider and Kometer, 2010), have such a profound effect on mental wellbeing are manifold. For one, psilocybin may foster processing of traumatic events by enhancing autobiographical memory recall in trauma patients (Carhart-Harris *et al*., 2012b). Specifically, exposure to psilocybin was found to enhance recall of personal memories and emotions, especially increasing the vividness of these memories, underlined by an activation of the visual association cortex during the recall process (Carhart-Harris *et al*., 2012b). On the other hand, LSD was found to decrease the tendency to engage in mental time travel to the past, which is often associated with rumination and depressive thoughts (Speth *et al*., 2016). Psychedelics may further aid psychotherapeutic efficiency by enhancing suggestibility in patients. In an administration study, LSD was found to increase the subjective intensity of suggested psychobiological states, such as that one's arm was becoming heavier, or that water tasted especially refreshing (Carhart-Harris *et al*., 2015). In addition, psilocybin fosters "unconstrained cognition" in that it triggers a decrease in cerebral blood flow in brain regions that serve as structural "hubs" for information transmission between different brain regions and as systems for cognitive integration and constraint of external stimuli (Carhart-Harris *et al*., 2012a).

Apart from these basic cognitive and perceptual effects, the primary reason for the remarkable therapeutic efficiency of psychedelics seems to be their phenomenological effect on the user. In one of the rare cases of experimental research into the effects of psychedelics on healthy subjects - involving the double-blind administration of either an effective dose or a placebo/ control substance - Griffiths and colleagues (2006) found that psilocybin reliably induced self-reported "mystical experiences" in hallucinogen-naïve participants. A large portion of the participants rated the experience as "having substantial personal meaning and spiritual significance" (p. 279), and a staggering 67% considered it to be among the top five meaningful experiences of their life. Two months after their treatment, 79% of participants reported increases in life satisfaction, and community observers rated participants' overall behavior to have changed for the better. Further indicating long-lasting effects of the experience, a 14-month post-treatment follow-up revealed positive changes in participants' self-reported attitudes about life, mood, (altruistic) social effects, general behavior, and life satisfaction (Griffiths *et al*., 2008). A follow-up study replicating these findings produced initial evidence that psilocybin administration produces dose-dependent persisting increases in life satisfaction, spirituality, and overall happiness (Griffiths *et al*., 2011). In particular, the mystical experience seems to have affected participants' core personality, as suggested by increased self-reported openness to experience after participating in the study (MacLean *et al*., 2011). Such lasting effects on core personality traits - which are usually thought of as comparably stable - may help explain some of the aforementioned promising effects of psychedelics in the treatment of addiction and mood disorder, two classes of clinical conditions which were theorized to be rooted in the rigid maintenance of certain maladaptive personality traits (Ball, 2005; Swendsen *et al*., 2002).

These results are further supported by a large-scale population survey, which, despite the widely held belief that psychedelic substances have negative effects on mental and physical health (Johansen and Krebs, 2015), established a positive relation between lifetime experience with psychedelics and mental wellbeing, manifesting in reduced psychological distress and suicidality (Hendricks *et al*., 2015). Experience with other classes of substances, the survey found, was more likely to have a negative effect on these variables. Importantly, this effect cannot be fully explained by hedonistic experiences caused by these substances, as psychedelics can acutely heighten anxiety, paranoia, and confusion (Griffiths *et al*., 2011). Yet, although psychedelic experiences can be unpleasant and challenging, a recent survey found that 84% of users who did experience such a "bad trip" endorsed benefiting from it in the long run (Carbonaro *et al*., 2016). In fact, the more difficult the challenging experience was, the more it predicted self-reported enduring increases in life satisfaction resulting from the experience.

Psychedelics and nature

One common mystical experience encountered by many during the psychedelic state is a profound feeling of connectedness or unity - a presumed consequence of a loss of self-awareness or ego-dissolution (Tagliazucchi *et al*., 2016). Specifically, psychedelics were found to decrease integrity *within* brain networks while simultaneously increasing functional connectivity *between* different brain networks, which correlate with self-reported experiences of ego-dissolution (Carhart-Harris *et al.*, 2012a). Primarily, increased connectivity between brain networks associated with self-awareness and introspection - for example, the default mode network - was found to attenuate the functional identity of these networks, causing the lines between self and environment to blur (Tagliazucchi *et al.*, 2016). In fact, in recent psilocybin administration studies, participants reported experiencing, for example, a "feeling of no boundaries, where I did not know where I ended and where my surroundings began" or that they felt "with every sense and fiber of my being that all things are connected" (Griffiths *et al.*, 2008, p. 629). In accordance, administration of psilocybin produced dose-dependent increases on a questionnaire assessing the construct of *external unity*, that is, feelings of interconnectedness with some objects from the external world.

According to a considerable number of anecdotal reports, ranging from Aldous Huxley to Albert Hofmann, such experiences of unity oftentimes manifest in a sense of connectedness with all living beings, certain plants and animals, or nature as whole. Notably, Masters and Houston (1966) observed their subjects to actively seek out natural settings for their psychedelic experiences.[1] Natural environments, the authors argue, facilitate a unique empathic connection with one's surroundings, the kind of which is not typically encountered in artificial environments. In fact, the authors' reasoning is supported by contemporary evolutionary psychologists' perspective on the human-environment fit. Specifically, although not explicitly mentioning psychedelic substances, the biophilia hypothesis argues that because humans have evolved in the Savannah, they now have an innate preference for such natural environments (Kellert and Wilson, 1995). This hypothesis is supported by abundant findings showing that perceptual exposure to nature has substantial physical and mental health benefits (for a review, see Maller, *et al.*, 2006), and that people have aesthetic preferences for natural environments - be it in art, such as the picture of a landscape, or in real life, such as a park in an urban area (Orians and Heerwagen, 1992). Thus, the intuitive appreciation of natural environments may contribute to the fact that many people anecdotally choose such settings for psychedelic experiences (cf. Erowid Experience Vaults, 2017, for a large selection of such anecdotal reports), which may in turn explain the frequency of reports about feelings of "profound levels of identification or merging with the natural world" (Strassman *et al.*, 2008, p. 277) during the psychedelic state.[2]

This substance-induced self-nature overlap can potentially be understood as a consequence of the ego-dissolution experienced under the influence of psychedelics (Tagliazucchi *et al.*, 2016), and may have unique cognitive and behavioral consequences for the person experiencing it. Social psychological research shows that self-other overlap can be understood as an embodiment of a close relationship, and that it is intimately linked to empathic concern (Aron *et al.*, 1991). Moreover, it typically causes an incorporation of the target's features into the self (Aaron *et al.*, 1991), and conversely, an ascription of one's own characteristics to the target (Galinsky *et al.*, 2005). In case of non-human entities (such as objects found in nature), the latter allows the ascription of uniquely human properties such as mental states (e.g. goals, intentions, desires, emotions) to these entities - a process referred to as anthropomorphism. This could explain why typical experiences by users of classic psychedelics, who took these substances in natural environments, include self-reported encounters with an "earth soul", mother nature, or spirits associated with the hallucinogenic plants themselves (e.g. Kjellgren *et al.*, 2009; Luke, 2011). Such notions can also be frequently encountered in cultures with animist belief systems that have a history of hallucinogenic plant use. These cultures often ascribe a spirit to plants and consider them embodiments of deities that communicate with human beings through their visions (e.g. Luna, 1984; Shanon, 2002, p. 14).

Attributing a mind and feelings to an entity is a process commonly referred to as mind perception. As put by Gray *et al.* (2012), mind perception can be considered the "essence of morality", in that it enables empathic concern for any given entity. Acknowledging that an entity has emotions and feelings is a prerequisite for considering it a moral patient, that is, something that can feel pain and that should hence not be harmed. In line with this reasoning, anthropomorphizing certain elements of nature was found to foster an empathic connection with the natural world (Tam *et al.*, 2013). An evocation of empathy, in turn, is one of the central causes for altruistic behavior, which - in the case of nature - would manifest in increased pro-environmental behavior.

In fact, some indigenous cultures that anthropomorphize natural elements in their religious beliefs indeed engage in more pro-environmental behavior than do neighboring cultures that do not share such an animist belief system (Atran *et al.*, 2002). Tam and colleagues (2013) were among the first to examine this relationship in more detail. They found that anthropomorphism positively predicts conservation behavior and that this relationship is indeed partially explained by empathic feelings towards nature. A similar effect was found for children in Western societies: those children who tended to ascribe mental and emotional qualities to natural entities showed heightened concern for their wellbeing (Gebhard *et al*., 2003). Likewise, adults with a general tendency to anthropomorphize non-human entities were also more likely to report to engage in pro-environmental behavior (Waytz *et al*., 2010). Lastly, there are findings showing that inducing people to take the perspective of an animal - thereby increasing self-other overlap with that animal - increased pro-environmental concern and behavior (Berenguer, 2007).

In sum, there is an empirical connection from psychedelics to experiencing unity and connection with one's environment to empathy-related phenomena and pro-environmental behavior. Based on this indirect link, we designed the present research to test the hypothesis that lifetime experience with classic psychedelics uniquely predicts nature relatedness - specifically, an internal identification with nature - and engagement in pro-environmental behavior. We expect the perceived unity with nature that people typically experience during the psychedelic state to have lasting effects on their personality that persist even after the experience ended. We further contend that the variables have a linear relationship: Frequency of the psychedelic experience, we theorized, would predict degree of engagement in pro-environmental behaviors.

There are two main reasons why observing this direct connection would be of great societal relevance. Firstly, there are manifold benefits on the individual level. Research finds positive relationships between connectedness to nature and happiness as well as other forms of wellbeing (for a recent meta-analysis, see Capaldi *et al*., 2014). Secondly, at a time when the "warming of the climate system is unequivocal" and the "human influence on the climate system is clear" (IPCC, 2014, p. 40), behaviors aimed at the protection of our environment are undeniably crucial. As Roszak *et al*. (1995) suggested, it should be a common goal to heal the fundamental alienation between humans and nature, thereby aiding in the conservation of our planet, by highlighting the reciprocity of their relationship, that is, to increase awareness and acceptance of people's "ecological self". Identifying factors that contribute to this process is therefore an important scientific endeavor - for individual wellbeing as well as for our planet's future.

Methods and results

Variables included in theoretical model

Lifetime experiences with psychedelic substances

Various substances have been classified as "psychedelics" or "hallucinogens" in the past, although pharmacology and psychological effects of these substances can be vastly different (Masters and Houston, 1966; Nichols, 2004). In line with Johnson *et al*. (2008) we focused on four separate classes of substances:

Classic Psychedelic substances. In the present research, we were interested in the unique effects of experience with classic psychedelic substances - or hallucinogens (Nichols, 2004) - on nature relatedness and pro-environmental behavior. These substances are usually characterized by their action as 5-HT_{2A} receptor agonists (Nichols, 2004; Vollenweider and Kometer, 2010). In addition to the effects described above, they cause a long list of somatic (e.g. dizziness, nausea), perceptual (altered shapes and colors, synesthesia), and psychological symptoms (alterations in mood, depersonalization, dreamlike states, hallucinations) (Hollister, 1984; Nichols, 2004). Classic psychedelic substances can be broadly divided into two sub-classes of compounds - tryptamines and phenethylamines.

Classic psychedelic tryptamines include psilocybin, found in various species of the *Psilocybe* genus of mushrooms, dimethyltryptamine (either *N,N*-DMT or 5-MeO DMT), found in hundreds of species in the plant and animal kingdom, d-lysergic acid diethylamide (LSD), a semi-synthetical ergotamine derivate, and ibogaine - an alkaloid found in the *Tabernathe iboga* plant native to West-Central Africa. Ibogaine also acts as a N-methyl-Daspartate (NMDA) receptor antagonist and weak κ-opioid receptor agonist, and can therefore induce symptoms typical of dissociative anesthetics. We decided, however, to group ibogaine with the classic psychedelic substances, as its primary phenomenological effects are believed to be rooted in 5-HT_{2A} receptor affinity (Brown, 2013).

Phenethylamines include mescaline, a compound primarily found in the *Lophophora* and *Echinopsis* genera of cacti (such as Peyote or San Pedro), as well as synthetic compounds such as 2C-B, 2C-E, DOx, or DOM (Shulgin and Shulgin, 1991), which also primarily act upon the 5-HT_{2A} receptor.

Dissociative Anesthetics. The class of dissociatives primarily comprises the atypical anesthetic ketamine (an NMDA receptor antagonist), the over-the-counter cough suppressant dextromethorphan (DXM), phencyclidine (PCP), and newer research chemicals such as methoxetamine (MXE) (Corazza *et al*., 2012). Some of their effects are comparable to the ego-dissolving effects of classic psychedelics. Dissociatives can distort proprioception and sensory perception, and can cause a detachment from one's physical body and the external environment - symptoms referred to as depersonalization and derealization (Curran and Morgan, 2000). In higher doses, dissociatives can cause a "state of wildly dissociated experiences in which other worlds or dimensions that are difficult to describe in words are said to be perceived, all the while being completely unaware of one's individual identity or the outside world" (Pai and Heining, 2007: 62-63). We thus included experience with dissociatives in our model, as they are likely to correlate with frequency of psychedelic experiences and because of their potential effect on self-nature overlap as a function of self-expansion.

Empathogens - sometimes also referred to as entactogens (Nichols, 1986). Chemically related to both classic psychedelics and stimulants, empathogens are a class of substances characterized by their effects on emotional openness, "empathic resonance", and personal relatedness to other human beings. Prominent exemplars include the widely used recreational substances MDMA (or "Ecstasy") and MDA. We included empathogens in our model, since - as outlined above - pro-environmental behavior can be framed as an empathic reaction towards nature, that may be strengthened by experiences with empathogens. In fact, one of MDMA's features that makes it especially suitable in aiding the treatment for post-traumatic stress disorder (PTSD; Mithoefer *et al*., 2011) is its increase in empathic social interaction (Sessa, 2016; Vollenweider *et al*., 1998) and pro-social feelings (Dumont *et al*., 2009) that may in theory similarly extend to encompass the entirety of the natural world.

Natural deliriants. This class of substances comprises anticholinergic tropane alkaloids such as atropine, hyoscyamine, and scopolamine, commonly found in plants such as datura, belladonna, mandrake, or henbane. As their psychotropic effects - characterized by vivid hallucinations and confusion - are frequently described as extremely unpleasant and consumption can have fatal consequences (e.g. Boumba *et al.*, 2004), most people nowadays refrain from recreationally consuming natural deliriants. However, their historic use as natural hallucinogens and dissociatives (Rudgley, 1995) qualifies them for inclusion in our model. Further included in this category are GABAA agonists such as muscimol and ibotonic acid, typically found in mushrooms of the *Amanita* genus.

Control variables

In addition to the various classes of psychedelic substances listed above, we included a selection of covariates in our model for which we had direct predictions with regard to their relation to psychedelic drug consumption and nature relatedness. These covariates include experience with two other classes of psychoactive substances as well as three personality traits.

Cannabinoids. This class of substances comprises tetrahydrocannabinol (THC), the principal psychoactive compound found in cannabis, and synthetic variants of it. Cannabis was included in the model because of its historical entheogenic use in religious ceremonies (Courtwright, 2001), and the fact that it is the most commonly consumed illicit substance in the United States (Center for Behavioral Health Statistics and Quality, 2015). Further, it is strongly associated with counterculture and liberal politics (e.g. Bachman *et al.*, 1980), both of which are positively related to pro-environmental behavior (Feinberg and Willer, 2013). In fact, research found that adolescents prefer to consume cannabis in natural settings, and reported increased feelings of reconnection with the natural world (Moffat *et al.*, 2009).

Popular legal drugs. To assess whether a mere appreciation of mind-altering substances could explain a potential effect of psychedelics on nature relatedness in our model, we included a class of substances comprising the three most-consumed legal psychoactive substances in the United States - and probably the world - namely caffeine, nicotine, and alcohol (Center for Behavioral Health Statistics and Quality, 2015).

Conscientiousness. Lastly, we added to three personality variables to our model. The personality trait of conscientiousness, one of the so-called "Big 5" personality traits, describes individual differences in propensity to follow socially prescribed norms and rules (Gosling *et al.*, 2003). In our model, we included this variable both as a predictor of nature relatedness and pro-environmental behavior. In line with the literature, we expected conscientiousness to be negatively correlated with consumption of unhealthy or illegal substances (as one is not "supposed to" engage such behaviors) (Bogg and Roberts, 2004), and positively associated with pro-environmental behavior and ecological concern (Nisbet *et al.*, 2009).

Openness to experience. As a second covariate, we decided to include the personality trait of openness to experience in our theoretical model (Gosling *et al.*, 2003). Openness was found to be positively associated with non-conformity and positive attitude towards psychoactive drugs (e.g. Mabry and Khavari, 1986), as well as with positive attitudes towards nature (Nisbet *et al.*, 2009). We therefore theorized that this variable would predict both consumption of psychedelic substances and nature relatedness.

Political conservatism. Lastly, we included political conservatism as covariate in the model, using it to predict both nature relatedness and pro-environmental behavior. Political conservatism was found to be negatively correlated with recreational drug attitudes (Kurzban *et al.*, 2010), and is historically related to drug prohibition and to authoritarianism rather than liberal worldviews. Right-wing authoritarianism was similarly found to be highly negatively correlated with environmental concern (Schultz and Stone, 1994). We thus expect this personality variable to negatively predict both experience with psychedelic substances and pro-environmental behavior, thereby potentially accounting for any effect we might find between those two constructs.

Nature relatedness

As a potential mediating process, we included Nisbet and colleagues' (2009) construct of nature relatedness in our model. Nature relatedness is a considerably stable personality trait that captures people's ecological self-construal, or ecological identity, and thus centers around their perceived connectedness with the natural world. Unlike past constructs, it includes people's affective, cognitive, as well as physical relationship with nature, and therefore involves both people's concrete feelings towards outdoor environments, as well as their abstract understanding of their interconnectedness with all living beings on this planet. According to the authors, the construct of nature relatedness (NR) can be separated into three sub-dimensions, labeled NR-Self, NR-Perspective, and NR-Experience, representing different facets of a person's relationship with the natural world (Nisbet *et al.*, 2009).

NR-Self. This dimension represents people's internalized identification with nature, and therefore most closely describes their ecological identity. It reflects feelings and thoughts about one's personal relationship with nature, exemplified by agreement to questionnaire items such as "I feel very connected to all living things and the earth" or "I am not separate from nature, but a part of nature". In line with our hypothesis outlined above, we expected this factor to be primarily affected by experience with classic psychedelic substances, as they seem to broaden people's self-construal and to facilitate incorporate of external objects and entities into the self.

NR-Perspective. This second sub-dimension captures people's external, nature-related attitudes and behaviors, and revolves around the environmental impact of individual human actions as well as humanity's general negative impact on the planet. This sub-dimension is exemplified by questionnaire items such as "Humans have the right to use natural resources any way we want" (reverse-coded) or "The state of nonhuman species is an indicator of the future for humans". Although this dimension is conceptually closest to pro-environmental behavior, we expected it to be affected by experience with classic psychedelics to a lesser extent, when accounting for its intercorrelation with the other two sub-dimensions.

NR-Experience. The third sub-dimension of the nature relatedness construct is NR-Experience. It captures people's affect-based attitudes towards actual nature-related experiences, and revolves around people's attraction to nature and their desire of being in a natural environment. According to Nisbet and colleagues (2009), this aspect of nature relatedness can be found, for example, in people who are "drawn to the wilderness, and who are aware of and fascinated with nature all around them". It is exemplified by questionnaire items such as "My ideal vacation spot would be a remote, wilderness area" or "I enjoy digging in the earth and getting dirt on my hands". As this sub-dimension is based on feelings of familiarity - or a close relationship - with nature, we expected it to be similarly affected by experience with classic psychedelic substances.

Pro-environmental behavior

As our main dependent variable, we included self-reported pro-environmental behavior in our theoretical model. Because we were interested in a broad range of pro-environmental behaviors, we followed an approach by Whitmarsh and O'Neill (2010), and focused on 12 so-called "headline behaviors" (some of them assessed by multiple items) that were established by the UK DEFRA (2008). These behaviors comprise actions that have both low and high impact on the environment. In addition, some of them are one-off, while others need to be performed on a regular basis. According to Whitmarsh and O'Neill (2010), these actions tap into four general areas of pro-environmental concern: domestic energy/water use (e.g. more responsible water use), waste behavior (e.g. more recycling), transport (e.g. less flying), and eco-friendly shopping (e.g. buying more environmentally friendly products). We decided on following this approach of assessing pro-environmental concern, as we wanted to focus on everyday pro-environmental behavior that is (for the most part) not immediately related to the nature relatedness construct outlined above. That is, our goal was to capture behaviors that affect nature more indirectly, rather than behaviors that are directly aimed at protecting nature, such as saving the rainforest or planting trees.

In our model we expected pro-environmental behavior to be affected by the different sub-dimensions of nature relatedness (Nisbet *et al.*, 2009). That is, any effect that experience with psychoactive substances may have on pro-environmental behavior, we expected to be mediated by one of these sub-dimensions.

Participants and design

In total, 1501 participants, recruited from Amazon.com's Mechanical Turk website, completed the study in exchange for modest financial compensation. Out of these participants, 14 were excluded from data analysis, as they indicated that they responded to one or more items randomly or in a purposefully wrong manner. This left us with a final sample of 1487 participants (913 female, 566 male, 8 other), with a mean age of 35.77 years (SD = 11.88), and an age-range from 18 to 78 years (Table 1).

Table 1. Demographics

Sample characteristics (*n* = 1487)		Frequency (Percentages)
Gender		
	Male	566 (38.1%)
	Female	913 (61.4%)

	Low (1 to 3)	291 (19.6%)
	Medium-Low (4 to 5)	491 (33.0%)
	Medium-High (6 to 7)	589 (39.6%)
	High (8 to 10)	116 (7.8%)
Political preference: 1 (strongly liberal) to 7 (strongly conservative)		
	Liberal (1 to 2)	496 (33.4%)
	Moderate (3 to 5)	782 (52.6%)
	Conservative (6 to 7)	208 (14.0%)
Drug attitudes: 1 (extremely negative) to 7 (extremely positive)		
	Very negative (1 to 2)	644 (43.3%)
	Moderate (3 to 5)	723 (48.6%)
	Very positive (6 to 7)	120 (8.1%)

Mechanical Turk is a so-called crowdsourcing website, on which users can complete minor tasks, such as participating in a research survey, in exchange for small monetary incentives. It allows for rapid collection of data from a sample that is surprisingly representative of the US population - oftentimes more so than samples obtained through census-representative web-panels (Redmiles *et al.*, 2017) - especially when it comes to gender and ethnicity of participants. Participants on Mechanical Turk, however, tend to be younger and more educated than the general population (Pew Research Center, 2017). Although participants take part in these studies using their own electronic devices (e.g. PCs, mobile phones), data quality matches (and sometimes exceeds) that achieved through traditional means of data collection, such as laboratory studies (Buhrmester *et al.*, 2011; Goodman *et al.*, 2013; for a review see Paolacci and Chandler, 2014), despite the fact that participants are highly experienced in participating in psychological surveys (Rand *et al.*, 2014). Past research has already made use of Mechanical Turk to collect data from clinical populations (Shapiro *et al.*, 2013), and it was successfully used in drug-related surveys, for example in a study of daily alcohol consumption (Boynton and Richman, 2014). Although the sample is to some extend self-selected (as is the case for most panel data), increased anonymity of the respondents may actually foster more honest and less socially desirable responding, especially when it comes to sensitive topics such as consumption of illicit substances (see Krumpal, 2013 for an overview).

Materials and procedure

First, participants completed a newly developed questionnaire, assessing their lifetime experience with 30 psychoactive substances. For each substance, participants were asked to indicate on a binary measure whether they "ever took it for recreational purposes - that is, when [it was] not taken for treatment of a medical condition". If they answered "yes" they were prompted to indicate on a scale ranging from 1 (*very rarely*) to 5 (*very often*) how often they took the respective substance in the past. If a participant indicated that he or she had no experience with a given substance, they received a score of "0" (see Supplementary Information for the entire list of substances).

Subsequently, participants worked on the Nature Relatedness Questionnaire by Nisbet and colleagues (2009), assessing their individual relationship with nature on three unique dimensions. Specifically, participants were asked to indicate their agreement with 21 statements using a scale ranging from 1 (*strongly disagree*) to 5 (*strongly agree*). Items included statements such as "My ideal vacation spot would be a remote, wilderness area" or "Animals, birds and plants should have fewer rights than humans" (reverse-coded).

Subsequently, all participants proceeded to work on a second questionnaire assessing their self-reported frequency of engaging in various pro-environmental actions. To that end, they were asked to indicate for a selection of 17 pro-environmental actions, taken from Whitmarsh and O'Neill (2010), how often (if at all) they take each action, using a 4-point scale labeled 1 (*never*), 2 (*occasionally*), 3 (*often*), and 4 (*always*).[3]

At the end of the survey, participants responded to the Ten-Item Personality Inventory (Gosling *et al.*, 2003) as a short assessment of the "Big Five" personality traits. Specifically, participants were presented with 10 statements, each beginning with "I see myself as ____", followed by two adjectives related to personality (e.g. "Anxious, easily upset"). For each statement, participants were asked to indicate their agreement using a Likert-type scale ranging from 1 (*strongly disagree*) to 7 (*strongly agree*).

Lastly, we assessed a set of demographic variables. Participants indicated their age, gender (*male, female, other*), ethnicity (*Black, White, Hispanic, Native American, Asian, other*), sexuality (*straight, gay/lesbian, other/none*), whether English was their first language (*yes, no*), their highest level of education (*school, high school, college, bachelor, master, PhD/MD*) including which subject they majored in, their self-assessed socio-economic status (i.e. "your or your family's economic and social position in relation to others"), from 1 (*very low*) to 10 (*very high*), their general attitude towards psychoactive substances, from 1 (*extremely negative*) to 7 (*extremely positive*), and their political orientation, from 1 (*strongly liberal*) to 7 (*strongly conservative*). As a data exclusion criterion, we asked participants on a binary item, whether they answered one or multiple questions in a random (or purposefully wrong) manner.

Results

Experience with psychedelic drugs

Of all participants, 26.9% indicated previous experience with at least one classic psychedelic substance (Figure 3). Notably, this number is substantially greater than the approximately 13.6% found in the NSDUH study of the Substance Abuse and Mental Health Services Administration of the United States Department of Health and Human Services for the years 2008 to 2012 (Hendricks *et al.*, 2015).

Post-hoc modifications to the model

We modified our theoretical model in two noteworthy ways. First, we had to drop the latent variable for natural deliriants from the model, as less than 1% of our sample had experience with any of the three substance groups that comprise it (i.e. 3, 5, and 11, people, respectively). That is, overall experience with these substances was too low to interpret any potential results. Second, we analyzed modification indices of the model and found that additional covariation between the indicator variables "other psychedelics" and "other dissociatives", β = 0.251, *SE* = 0.025, *p* < .0000001, 95%CI = [0.201; 0.300], as well as "other psychedelics" and "other empathogens", β = 0.329, *SE* = 0.024, *p* < .0000001, 95% CI = [0.282; 0.376], meaningfully improved model fit (Figure 1). Theoretically, this covariation could be explained by a personality variable that fosters interest in rare psychoactive substances, a tendency to consume unknown substances, or forgetfulness with regard to consumed substances.

Figure 1. Structural equation model for Model 1. All values indicate standardized regression coefficients. Significant paths ($p < .05$) are displayed in black, marginally significant paths ($p < .10$) are displayed stroked, non-significant paths are displayed in gray.

Structural equation model

To keep the number of indicators in our model at a minimum and thereby reduce the chance for estimation errors, indicators for the three nature relatedness subscales were parceled once, while the 17 indicators for pro-environmental behavior were parceled twice, following the procedure recommended by Little *et al.* (2002). Data analysis was performed in R 3.2.3 (R Core Team, 2015), using the LAVAAN Package for structural equation modeling (Rosseel, 2012). Models fit estimates were obtained through full information maximum likelihood estimations (FIML). The overall model fit turned out to be acceptable, indicated by comparative fit index (CFI) = .889, Tucker-Lewis Index (TLI) = .869, and root mean square error of approximation (RMSEA) = .052, 90% CI = [.050; .054].

All indicators significantly contributed to their respective latent variables. As predicted, all exogenous variables were highly intercorrelated (Figure 1). That is, lifetime experience with a given substance class always covaried with experience with a different substance class (all p values $< .001$). As further predicted, the personality dimensions of conservatism (all p values $< .001$) and conscientiousness (all p values $< .01$) were negatively related to experience with each substance class, while openness to experience was positively related to these experiences (all p values $< .0001$). In a similar manner, the three subscales of nature relatedness significantly covaried with one another: NR-Experience with NR-Perspective, $\beta = 0.356$, $SE = 0.033$, $p < .0000001$, 95% CI = [0.291; 0.422], NR-Experience with NR-Self, $\beta = 0.724$, $SE = 0.020$, $p < .0000001$, 95% CI = [0.685; 0.763], as well as NR-Perspective with NR-Self, $\beta = 0.746$, $SE = 0.021$, $p < .0000001$, 95% CI = [0.704; 0.788].

Importantly, in this model, 14 significant and three marginally significant regression paths emerged (see Figure 1). In line with our main hypothesis, lifetime experience with classic psychedelic substances positively predicted two subscales of nature relatedness, NR-Self, $\beta = 0.303$, $SE = 0.081$, $p < .001$, 95% CI = [0.144; 0.462], and NR-Experience, $\beta = 0.256$, $SE = 0.087$, $p = .003$, 95% CI = [0.086; 0.427]. In other words, participants who had more experience with classic psychedelics were more inclined to see nature as a part of their selves, and had a greater propensity to enjoy being in a natural environment, independent of their history with other (related or unrelated) classes of psychoactive substances, their core personality traits, or their political orientation. Our data thus suggest that classic psychedelics have a unique effect on how people perceive themselves in relation to nature that persists long after the experience ended.

While none of the other substance classes significantly predicted any of the three nature relatedness subscales, three marginally significant regression paths emerged. First, in addition to the significant paths reported above, lifetime experience with classic psychedelics also positively predicted the third NR subscale, that is, NR-Perspective, hinting at a broader effect of experience with classic psychedelics on various facets of nature relatedness, $\beta = 0.150$, $SE = 0.087$, $p =.085$, 95% CI = [-0.021; 0.321]. In addition, two unpredicted pathways emerged. For one experience with dissociative anesthetics negatively predicted NR-Perspective, $\beta = -0.210$, $SE = 0.110$, $p =.056$, 95% CI = [0.426; 0.006], while experience with popular legal drugs positively predicted the experience dimension of nature relatedness, $\beta = 0.145$, $SE = 0.077$, $p =.059$, 95% CI = [-.006; 0.296]. Notably, though, these marginally significant paths turn non-significant when the model is slightly altered (see below).

As further hypothesized, the three nature relatedness subscales were each significantly predicted by all three of our personality-related control variables (all p values $< .017$). While conscientiousness and openness to experience both positively predicted all three sub-dimensions of nature relatedness, political conservatism had a more complex relationship with the construct: It was (expectedly) negatively related to NR-Perspective and NR-Self, yet positively related to NR-Experience (Figure 1). Importantly, when accounting for the intercorrelation of the nature relatedness subscales, the NR-Self dimension exclusively predicted pro-environmental behavior. That is, the more people perceived nature to be an integral part of their selves, the more they reported engaging in various pro-environmental behaviors, $\beta = 0.638$, $SE = 0.086$, $p < .0000001$, 95% CI = [0.470; 0.806]. The two other sub-dimensions of nature relatedness did not predict engagement in these behaviors. That is, despite their interrelation, only the dimension of nature relatedness associated with people's self-construal ultimately affected their self-reported ecological behavior in our model.

Finally, both conscientiousness, $\beta = 0.070$, $SE = 0.023$, $p =.002$, 95% CI = [0.026; 0.114], and political conservatism, $\beta = -0.064$, $SE = 0.028$, $p =.025$, 95% CI = [-0.119; -0.008], directly predicted self-reported engagement in pro-environmental behavior in the hypothesized directions.

Mediation analysis

As lifetime experience with classic psychedelics exclusively predicted the NR-Self dimension, and this dimension uniquely predicted participants' self-reported pro-environmental behavior, we tested whether this indirect path would explain any direct effect of experience with psychedelics on pro-environmental behavior. We therefore added an additional direct path from the latent variable for classic psychedelics to pro-environmental behavior to our model, in order to test for statistical mediation. Inclusion of this additional path affected neither the overall model fit nor the significance of any of the regression paths in the model.

As depicted in Figure 2, we found that increases in NR-Self indeed mediated the effect of experience with classic psychedelics on pro-environmental behavior. The total effect of lifetime experience with psychedelics on this variable was highly significant, $\beta = 0.231$, $SE = 0.056$, $p < .001$, 95% CI = [0.114; 0.347]. Importantly, however, we found a statistically significant indirect effect, $\beta = 0.182$, $SE = 0.056$, $p = .001$, 95% CI = [0.073; 0.292]. Controlling for this indirect effect substantially weakened the direct effect and turned it marginally significant, $\beta = 0.048$, $SE = 0.026$, $p = .061$, 95% CI = [-0.002; 0.099]. In other words, the effect of lifetime experience with classic psychedelics on pro-environmental behavior is partially accounted for by the extent to which people's self-construal incorporates the natural world.

Alternative models

See Table 2 for additional model comparisons. In Model 2 we included demographic covariates, using them to predict both the three subscales of nature relatedness and pro-environmental behavior. Model 3 was identical to Model 2 with the addition of the three remaining personality variables from the "Big 5". In general, inclusion of additional variables and regression paths decreases model fit, but we found no change in (non) significance of the paths. As a notable exception, the marginally significant paths from Model 1 (see above), turn non-significant with the inclusion of additional covariates. Lastly, Model 4 was identical to Model 1, but replaced the three NR-Subscales with a single overall NR-Score (cf. Nisbet *et al.*, 2009). Here, too, classic psychedelics remained the only significant predictor of nature relatedness. In all alternative models, we found a statistically significant mediation of the NR-Self dimension (or in Model 4 the overall NR-Score) in the relationship between lifetime experience with classic psychedelics and pro-environmental behavior.

Summary

We found a linear relationship between lifetime experience with classic psychedelic substances and scores on two sub-dimensions of nature relatedness, NR-Self and NR-Experience. The more people had experience with classic psychedelics, the more they enjoyed spending time in nature, and the more they construed their self as being a part of nature. None of the other substance classes included in our model significantly predicted any of the nature relatedness dimensions individually.

NR-Self, in turn, was the only dimension of nature relatedness that positively predicted self-reported engagement in pro-environmental behavior, and significantly mediated the relation between experience with classic psychedelics and pro-environmental behavior. That is, the perception of being part of the natural world - rather than being separate from it - that is heightened for people who have experience with classic psychedelics, is largely responsible for the increased pro-environmental behavior that these people report. Notably though, as the direct effect of experience with psychedelics on pro-environmental behavior remains marginally significant after controlling for the indirect effect, it is likely that it is not entirely driven by the mediating variable we identified. Which other factors may contribute to this effect, however, is for future research to determine.

General discussion

In the present research, we identified a novel predictor of nature relatedness and pro-environmental behavior. Results of our study tentatively suggest that experience with classic psychedelic substances may have lasting effects on the way people perceive nature and how strongly they engage in ecological behavior. Specifically, results show that lifetime experience with psychedelic substances (as opposed to other recreationally consumed substance classes) uniquely predicts self-reported nature relatedness, specifically the degree to which people incorporate nature into their self-construal, which in turn predicts self-reported engagement in pro-environmental behavior.

There are, however, a few shortcomings to our study. First and foremost, we did not gather causal evidence for the proposed link between the psychedelic experience and increased nature relatedness. Future studies may address this concern by testing how administration of some of these substances may affect nature relatedness and pro-environmental behavior in the short and long term. Correlational designs - such as the one employed in this research project - suffer from the disadvantage that the directionality of the effect observed is unknown. That is, from an empiric standpoint, it may equally be the case that people who feel greater nature relatedness have a greater propensity to take psychedelic drugs. Because of the correlational nature of our study, we can only argue against this proposition on a theoretical level. As stated in the introduction of this article, there is strong reason to believe that psychedelic substances increase nature relatedness as a function of their ego-dissolving effects (Tagliazucchi *et al*., 2016), with a multitude of anecdotal reports pointing in this direction. For the reversed link, however, this is not the case. There is no reason to believe that people who see nature as an integral part of their selves are more prone to taking psychedelic substances, but show no greater affinity to take other classes of psychoactive substances. For example, while many of the classic psychedelic compounds can be found in nature - thereby potentially explaining a correlation with nature relatedness - the same is true for cannabis, some opiates, tobacco, or deliriants, which did not have significant explanatory power in our study. Thus, the idea that natural substances are more likely to be consumed by people who feel a stronger relatedness to nature cannot explain the present results. In addition, it would be theoretically difficult to explain how specifically the NR-Self dimension - that is, the inclusion of nature in people's self-construal - would cause people to consume more psychedelic drugs, whereas this would not be the case for their general appreciation of being outdoors (NR-Experience) or strong political views with regards to environmental issues (NR-Perspective). Lastly, as the relationship we found remained significant after controlling for demographic variables and personality traits such as openness to experience, conscientiousness, or political attitudes, it is unlikely that the association we found can be entirely explained by a collection of personality traits stereotypically associated with psychedelic users (e.g. being of the "hippie" type).

Still, while theoretically less plausible, the present data cannot entirely rule out reverse causality or a hidden influence by a third variable that was not assessed in this study. Therefore, future research should focus on determining whether the effects reported here can be causally validated through experimental means. For example, in addition to administration studies, one way to rule out some of the concerns inevitably present in correlational designs is to test the hypothesis in more elaborate within-subject designs based on longitudinal data. Thereby it would be possible to track people's views on nature and their ecological behavior over time while investigating how consumption of psychedelic substances affects these trends.

Similarly, it would make sense to more thoroughly investigate whether the settings in which psychedelics are consumed potentially influence the degree to which they have an effect on people's nature relatedness. As argued above, the ego-dissolution and simultaneous merging of the self with the outside world that people typically experience under higher doses of psychedelic substances may constitute general, unspecific phenomena that only relate to people's perception of nature when the respective substance is taken in a naturalistic setting. In other words, potential administration or longitudinal studies should assess and manipulate where the substances are consumed, and whether this has an effect on the degree to which the natural world is incorporated into people's self-construal. In the same vein, it would be crucial for future research endeavors to further investigate the moderating role that degree of experienced eg-odissolution plays in the association between past experience with psychedelics and nature relatedness. As we found a linear relationship between both constructs, one could hypothesize that greater experience with psychedelics caused subjects to also consume higher doses of these substances, which in turn could have increased the likelihood of experiencing instances of severe ego-dissolution.

A second shortcoming concerns our main dependent variable in this study, that is, pro-environmental behavior. As we were working with an online sample, we were only able to assess this construct via participants' self-reports. Thus, one alternative interpretation to our findings could be that people who are open to taking psychedelic substances only *say* that they engage in more pro-environmental behavior without actually doing so. This is not to say that these people are more likely to exaggerate or claim falsehoods. It is possible that people who frequently take classic psychedelic substances cultivate a certain lifestyle that views eco-friendly behavior as ideal behavior. Both pro-environmental behavior as well as consumption of psychedelic substances may therefore be two aspects of a culturally propagated stereotype with which users of psychedelics may identify and respond to accordingly. In other words, what may be captured by our measure of pro-environmental behavior could be attributed to participants' ideal-self rather than their true self. Assessing true ecological behavior, however, is an empirically daunting task. One could implement tasks in which - for example - participants are given the opportunity to donate a certain percentage of their compensation to a pro-environmental cause, thereby assessing an actual behavior that has direct consequences for the environment. Hence, future research is needed to investigate actual effects on ecological behavior in more detail. Regardless, in order to investigate any real effects of psychedelic substances in this domain, it would be reasonable to not artificially reinforce these stereotypes and to evaluate use of psychedelic substances outside of their subcultural niches.

In sum, while correlational in nature, the present research tentatively suggests that experience with classic psychedelic substances may uniquely and positively affect people's relationship with nature, especially their self-construal with regard to how strongly they see themselves as being part of nature rather than being separate from it. This, in turn, seems to positively affect their everyday behavior, in that they report to make more ecology-friendly decisions in the domains of energy consumption, waste management, or shopping behavior. Should future studies investigating the causal relationship between psychedelics and nature relatedness confirm the present findings, it would suggest that certain unique experiences can alter people's perceived relationship with nature in a lasting manner. Specifically, such additional findings would confirm that psychedelic experiences can indeed contribute to a behavioral change fostering the caretaking of our environment, which - in light of the continuing destruction of our planet - is of critical importance. Abundant previous findings have suggested that psychedelic experiences can be physiologically and psychologically beneficial, while only very few negative consequences have been observed (e.g. Nutt *et al*., 2013). The present research aims at expanding this literature by providing initial support for the idea that psychedelic substances may positively affect people's perceived relationship with nature. Recent research revealed a growing trend of society's disconnection from nature, as becomes evident in cultural products (Kesebir and Kesebir, 2017). Reversing this trend would be beneficial for both the individual's mental and physical wellbeing and the environment (van den Bosch and Depledge, 2015). In fact, a recent meta-analysis revealed a positive relationship between perceived nature relatedness and positive affect, vitality, and life satisfaction (Capaldi *et al*., 2014). In addition, nature exposure was found to reduce rumination, a maladaptive pattern of self-referential thought associated with depression, thought to partially account for the correlation between urbanization and prevalence for mood-related mental illnesses (Bratman *et al.*, 2015). Therefore, a potential increase in nature relatedness as a consequence of experience with psychedelics may constitute a second pathway by which psychedelic experiences could exert their positive effects on mood and happiness, as demonstrated by recent work on their efficiency in the treatment of mood disorders (e.g. Carhart-Harris *et al.*, 2016). In light of these findings, the present results once more raise the question whether a continuing prohibition of these experiences is indeed a worthwhile pursuit.

Declaration of conflicting interest

The author(s) declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Funding

The author(s) received no financial support for the research, authorship, and/or publication of this article.

Notes

1. Although empirical evidence for these claims is scarce, some research shows that about 40% of adolescents have a general propensity to consume (for unspecified reasons) illicit substances outdoors (Hussong, 2000). Further, many adolescent cannabis users similarly report to prefer consuming this substance in outdoor settings, partly in order to establish a connection with the natural world (Moffat *et al.*, 2009).
2. In addition, other reasons for consuming psychedelics outdoors could be participants' desire to avoid disruption by sober individuals, avoid contact with law enforcement, or because some of the substances (such as psilocybin-containing mushrooms or peyote-containing cacti) can only be naturally encountered in the countryside, which may thereby indirectly foster their consumption in these settings.
3. Following these measures, we assessed two additional questionnaires for a different research project, fully unrelated to nature relatedness or pro-environmental behavior.

Abstract

The analysis of fruit bodies from species of the genera *Psilocybe, Gymnopilus, Inocybe, Conocybe* and *Pluteus* revealed the presence of psilocybin, psilocin and baeocystin in various collections from different countries.
Some investigations about the main synthesis of psilocybin and its derivatives were also carried out. Fruiting of various species could be demonstrated for the first time.
The spontaneous blueing of many of these mushrooms and mycelia as well as some directed biotransformation reactions will also be described.

In 1963, the appearance of an article by HOFMANN *et al.* [1] about the occurrence of psilocybin in European *Psilocybe semilanceata* (Fr.) Kumm. spurred renewed scientific investigation into psychotropic indole derivatives in mushroom species of Europe.

Psilocybe semilanceata (figure 1) is growing wild in Middle and North Europe as well as in other European countries, North- and South-America, Australia and very probably Asia.

The main alkaloids are psilocybin and baeocystin (4-phosphoryloxy-N-methyltryptamine) and in some cases only traces of psilocin [2-5].

For the first time baeocystin was isolated from this species in 1979 [5].

Habitats of the mushrooms are wet grassy fields and uncultivated pastures. The mushrooms grow on manured soil but not directly on dung. It seems than *Psilocybe semilanceata* is the most potent European hallucinogenic mushroom.

Fig. 1 - Naturally grown fruit bodies of *Psilocybe semilanceata* from the Duebener Heide, Germany (9/21/1989).

Samples show a considerable variation in the psilocybin levels of single fruit bodies (0.2 to 2.4% dry weight). But about 1% psilocybin was always determined if the average content from 10 to 20 mushrooms was analyzed. Baeocystin was found to occur along with small amounts of 4-phosphoryloxytryptamine (norbaeocystin).

I have cultivated some fruit bodies of *Psilocybe semilanceata* to determine determinate the alkaloid levels in comparison to naturally grown mushrooms.

Mycelium obtained from the spores of one mushroom was kept as a stock culture on 6% malt agar [6]. The spores can germinate after a storage of the dried mushrooms for 9 months at 20°C.

Fig. 2 - Fruiting of *Psilocybe semilanceata*. [in Erlenmeyer flask]

No indole derivatives have been detected in the mycelia from a surface culture of *P. semilanceata* on liquid malt extract media. In contrast to these results a fruiting of the species (figure 2) yielded fruit bodies with a similar high level of alkaloids as the naturally grown mushrooms (table 1).

This strain fruited after 3 to 4 months but other mycelia failed to form fruit bodies at all.

Table 1
Indole derivatives in fruit bodies of *Psilocybe semilanceata* from the cultivation on a sterile substratum with of compost, rice grain, grass seed, and water (12:3:4:22) after casing with peat/chalk.[6]
Content of dried mushrooms (%)

Flush No.	Psilocybin	Baeocystin
1	0.91	0.15
2	1.04	0.20
3	0.92	0.21
4	1.12	0.19

Fruiting of the subtropical species *Psilocybe cubensis* (Earle) Singer on a dung/rice grain substratum (figure 3) begins earlier than the formation of fruit bodies of *P. semilanceata* (3 to 4 weeks versus 3 to 4 months). But the former species failed to accumulate significant amounts of baeocystin. So both species are important for studying biochemical pathways of the formation of the tryptamine derivatives [7].

P. semilanceata is characterized by a blue-green coloration especially at the stem but blues inconsistently, mostly after several minutes to hours.

The use of this species ("liberty caps") as a hallucinogen is popular in Great Britain, Norway and other European countries for about 20 years. It seems that this mostly moderate use does not cause significant health problems.

Because of the high content of psilocybin dysphoric experiences were described in some cases as of overdoses. It is also well known that one's experiences with hallucinogens depend upon a host of experimental, cultural and psychological factors (setting and set) [8, 9].

Another interesting European species with strong psychoactivity is *Psilocybe bohemica* Sebek [9, 10].

These mushrooms were already found in Czechoslovakia near Sazava in 1942. They blue consistently after bruising and spontaneously in the age. The fruit bodies grow up to 15 cm high on humus and wood chips in the woods.

The species is widespread in Czechoslovakia [9] and it will probably be reported from many other European countries in the next years. Recent finds in Austria and Germany support this claim.

The analysis of fruit bodies revealed psilocybin, baeocystin and in some cases psilocin. Psilocybin levels varied from 0.11% up to 1.34% by dry weight [9]. The content of psilocybin and baeocystin was highest in the caps of the mushrooms (table 2).

Fig. 3 - The subtropical mushroom, *Psilocybe cubensis* [fruiting] on grain/dung without casing. [in Erlenmeyer flask]

Table 2
Amount of indole alkaloids in dried fruit bodies of *Psilocybe bohemica* (%)

Sample	Part of mushroom	Psilocybin	Psilocin	Baeocystin
1	fruit body	0.96	0.02	0.03
2	fruit body	1.34	-	0.01
3	fruit body	0.29	-	0.008
4	fruit body	1.12	-	0.02
5	fruit body	0.94	0.01	0.01
6	fruit body	0.22	0.01	0.02
7	cap	0.42	0.02	0.02
7	stem	0.12	-	0.01
8	cap	1.02	-	0.03
8	stem	0.50	-	0.01

Psilocybin was also found to be contained in the cultivated mycelia of this species. The amount ranged from 0.15% to 0.21% by dry weight in 6 different mycelia grown on 6% malt agar over 4 weeks. No other alkaloids were detected in the mycelial extracts.

A rhizomorphic to closely linear growth on the blueing mycelia was observed on soaked unsterilized cardboard (figure 4).

Fig. 4 - Mycelia of *Psilocybe bohemica* on soaked cardboard

Fruiting of the mycelia on rice grain/water mixture occurred without casing 12 weeks after inoculation (figure 5) but only if a temperature of 4°C was maintained for 3 days at the end of cultivation. This observation is in agreement with the occurrence on the naturally grown fruiting bodies in late autumn and early winter. Wild mushrooms of this species, differing from the cultivated mushrooms mainly by the absence of the 2 rings and the less robust habitat, have very similar other features, microscopic ones and the blueing in particular. The species required diffuse day light for pinhead initiation. Growth of the vegetative mycelia was observed on malt agar at 4°C.

Fig. 5 - Fruit body of *Psilocybe bohemica* on rice grain/water (1:2) 12 weeks after inoculation. [in Erlenmeyer flask]

In 1984 and 1986 Krieglsteiner had classified *P. bohemica* and the similar *Psilocybe serbica* Moser & Horak as *Psilocybe cyanescens* Wakefield [12, 13]. But some doubt still exists about the taxonomic conformity of different collections from Europe and North America.

For example, I have found, that the monokaryotic mycelia on *P. bohemica* and *P. cyanescens* do not form dicaryotic mycelia. Additionally, fruit bodies of *Psilocybe cyanescens* (U.S.A.) generally contained high amounts of psilocin [13, 14].

The recent discovery on hallucinogenic *Inocybe* species was a sensation in the study of the distribution of psilocybin and its derivatives in the fungal world. Until the 80s only muscarin was the classical toxin detected in a great number of the about 160 species of the genus *Inocybe*.

In 1965 J. FERENCZ found a new *Inocybe* species in Hungary. M. BABOS described these blueing mushrooms as *Inocybe aeruginascens* BABOS in 1968 (figure 6). Since 1980 *I. aeruginascens* has caused over 20 accidental hallucinogenic poisonings in East Germany because of some similarities with edible mushrooms like *Marasmius oreades* (Bolt.: Fr.) Fr. [9].

In all of these cases only euphoric experiences with hallucinations and illusions were reported. The mushrooms contained relative constant amounts of psilocybin, baeocystin and in some cases also tryptophan (table 3).

A new indole derivative, which I called aeruginascin, with a still unknown structure was also detected in this species [15-17]. We found only traces of psilocin in a few mushrooms but no muscarin at all.

A few months after my initial paper [17] other groups (for example [18]) have published about the occurrence of psilocybin in *I. aeruginascens*.

Table 3
Content of indole derivatives in dried mushrooms of *Inocybe aeruginascens* (%)

Sample	Psilocybin	Baeocystin	Aeruginascin
1	0.29	0.19	0.15
2	0.40	0.20	0.30
3	0.30	0.18	0.21
4	0.26	0.24	0.35
5	0.36	0.52	0.32

I. aeruginascens is characterized by a blue-green coloration of the stem after bruising or in a few cases spontaneously in the age.

After the detection of psilocybin in *I. aeruginascens* other alkaloid containing mushrooms like *Inocybe corydalina* Quel. or *Inocybe haemacta* (B. & Cooke) Sacc. were found. But in contrast to *I. aeruginascens* , which often grows in colonies of great numbers in parks of Germany and Hungary in grass on sand mainly in May or June, these species are very uncommon, growing in woods, and contain only small amounts of the psychotropic tryptamine derivatives. For example, *I. corydalina* accumulates about 0.01% to 0.03% psilocybin in the dried fruit bodies [18].

So only *I. aeruginascens* can cause significant accidental intoxications. I have isolated a mycelial strain of *I. aeruginascens* which degenerated completely after a few months of cultivation without further growth.

The greenish sclerotia and the brownish mycelia from the surface cultivation also contained about 0.1% psilocybin in the dried biomass.

Fig. 6 - Fruit bodies of *Inocybe aeruginascens* from Potsdam (Germany).

Another very interesting field of research is the occurrence of psilocybin in *Gymnopilus* species. Despite some old stories about possible intoxications with *Gymnopilus spectabilis* (Fr.) A. H. Smith from JapanJapon and some other hallucinogenic experiences with other species from North America no psilocybin could be detected in the genus *Gymnopilus* in Europe until 1988 [19].

In 1978 psilocybin was found in some North American species [19]. Since 1983 *Gymnopilus purpuratus* (Cooke & Mass.) Singer has been observed on heapes of mixtures of pig dung and wood chips in the district of Rostock, Germany. It seems that this blueing species was introduced from Argentina with grain used for forage in pig-breeding during last years. Recently the qualitative detection of psilocybin in extracts of *G. purpuratus* has been described [19]. In this investigation no quantitative analysis of the indole alkaloids was carried out.

In 1989 our own study on the amounts of psilocybin and its derivatives was published (table 4) [20]. It was found that the level of psilocin decreased appreciably during storage. No other species found in Europe contained such high amounts of psilocin like as *G. purpuratus*. Spores of *G. purpuratus* germinated quickly on malt agar.

Table 4
Indole alkaloids in *Gymnopilus purpuratus* (% dry weight)

Sample	Psilocybin	Psilocin	Baeocystin
1	0.29	0.28	0.05
2	0.31	0.29	0.04
3	0.21	0.20	0.03
4	0.28	0.31	0.04
5	0.33	0.28	0.05

The whitish mycelia blues consistently after bruising and after about 3 weeks of cultivation also spontaneously like old naturally grown fruit bodies. Fruiting of the mycelia on rice grain or sawdust and even mixtures occurred after 8 to 12 weeks after inoculation (figure 7). These cultivated mushrooms contained similar amounts of psilocybin and its derivatives as the naturally grown fruit bodies (table 5).

Table 5
Alkaloids in cultivated dried fruit bodies of *Gymnopilus purpuratus* (% dry weight)

Flush No.	Psilocybin	Psilocin	Baeocystin
1	0.13	0.15	0.03
2	0.15	0.18	0.02
3	0.23	0.21	0.04
4	0.18	0.21	0.05
5	0.15	0.14	0.02

Fig. 7 - Fruiting of *Gymnopilus purpuratus* on a rice grain medium. [in Erlenmeyer flask]

Psilocybin has also been found in *Pluteus salicinus* (Pers.: Fr.) Kumm. but this species is uncommon and grows on dead wood. STIJVE *et al*. detected only a mean concentration of 0.25% psilocybin in dried fruit bodies [21]. In my own investigations one collection contained about 1% psilocybin and traces of baeocystin as well as high amounts of urea [22]. In other dried samples I later found 0.4 to 0.6% psilocybin but no psilocin. I think much more investigations should be done to determinate the variation of the alkaloid levels in this species.

Often contradictory reports on hallucinogenic effects of species of the genus *Panaeolus* are explained in terms of differences in chemical composition due to geographical origin ("latent ability to form psilocybin").

Ola'h described such behavior during his investigations of the genus *Panaeolus* [23]. I think that this claim failed completely. All modern analytical investigations with HPLC and TLC including competent mycological examination yielded to a definitive composition of the species.

For example, STIJVE *et al*. [24] and my own investigation [25] could not detect psilocybin and its derivatives in one single mushroom of *Panaeolina foenisecii* (Fr.) Kü.

It seems that only *Panaeolus subbalteatus* (Berk. &Br.) Sacc. (figure 8) contains significant amounts of psilocybin in the genus *Panaeolus* in Europe [26]. All *Panaeolus* species are able to accumulate serotonin and its precursor 5-hydroxy-L-tryptophan as well as urea. I think that Ola'h has misinterpreted these compounds as psilocin because of his use of nonselective analytical methods.

In naturally grown mycelia and fruit bodies of *Panaeolus subbalteatus* there were significant differences in amounts and nature of the metabolites (table 6). Additionally it seems that much more work must be done to study the taxonomy and chemistry on *Panaeolus* species in Europe and even in the world.

Only a very few fruit bodies of *P. subbalteatus* show blueing [26]. In model reactions the oxidation of pure psilocin yielded bluish products [27]. Many enzymes can remove the phosphoric acid from psilocybin to form psilocin before oxidation.

Table 6
Indole derivatives in *Panaeolus subbalteatus* (% dry weight)

Substance	**Mycelium**	**Fruit bodies**
Psilocybin	0.07	0.08-0.70
Baeocystin	-	0.05-0.46
5-OH-L-tryptophan	-	qualitativ
Serotonin	0.10	0.08-0.30
L-Tryptophan	0.20	traces
Psilocin	-	-
Urea	-	1.8-2.3

The very rare species *Conocybe cyanopus* (Atk.) Kühn has been found only twice in East Germany in a period of 50 years. BENEDICT *et al*. found psilocybin in this species from North America, as did other authors later [28]. In Europe some mushrooms of this species contained psilocybin and traces of psilocin (for example the first analysis from Norway [29]).

In 5 naturally grown mushrooms from East Germany (1989) I found about 1% psilocybin and similar amounts of baeocystin as *P. semilanceata* can accumulate. The nonblueing mycelia grow on malt agar very slowly with formation of sclerotia, which also contained about 0.2% psilocybin.

The widespread occurrence of baeocystin in all European psilocybian species and in many other mushrooms from all over the world supports the hypothesis of REPKE *et al*. about the central role of this compound in the biosynthesis of psilocybin [30]. Mycelial cultures of *Psilocybe* species display a high capacity for hydroxylation of synthetic tryptamine derivatives at the 4-position. So specific biotransformations of *N,N*-diethyltryptamine and N-methyltryptamine were found [31].

In model investigations I have also found that the main synthesis of psilocybin and psilocin takes place in the biomass during the process of the formation of fruit bodies or sclerotia [32]. The total content of the alkaloids in the mycelia without fruiting or differentiation was comparatively low. In physiological old mushrooms of *Psilocybe cubensis* the spontaneous blueing is a sign of a significant decomposition of the alkaloids [32].

But in *P. semilanceata* , *I. aeruginascens* , and *P. subbalteatus* this oxidation process with slight blueing does not cause a significant destruction of psilocybin and baeocystin [5, 16, 26].

Fig. 8 - Cultivated fruit bodies of *Panaeolus subbalteatus* from dung/rice grain 92 days after inoculation. [in Erlenmeyer flask]

Part I.
The history of Teonanacatl, field work and culture work[1]

1. History

The use of hallucinogenic mushrooms in Mexico was reported by European and Mexican writers (11) centuries ago, and so is not news. Nor are mushrooms unique as hallucinogens. It is widely known that peyotl, *Lophophora williamsii* (Lem.) Coulter, a cactaceous plant likewise native to Mexico, contains a hallucinatory substance, mescalin. What is new in recent developments is the serious attempt to study the organisms responsible for these curious phenomena, an endeavor logically beginning at the biological level - *i.e.*, with a study of the mycological aspect of the rather complex problem. With this goes an attempt to obtain more details on the ethnobotanical role of the hallucinogenic mushrooms in southern and central Mexico. A consequence, and, to a certain degree, also a motive, of all this renewed interest in the subject is the extraction in pure form of a substance or substances important in medical research, or at least data on the active principle in these fungi which might throw light on phenomena of practical concern, such as the symptoms commonly referred to as schizophrenic, or the question of the maturity factor in neuroses.

Before the first specimens had come to the botanical laboratories, there had been some doubt whether the *teonanácatl* of the literature, a word supposedly meaning "sacred mushroom" in the Aztec language, was actually a mushroom rather than *Lophophora*. The word *teonanácatl* is here used in the sense of Schultes (13), Heim, and in fact the majority of the authors concerned with hallucinogenic mushrooms in Mexico (3, 10, 11, 12, 18, 19) - *i.e.*, as a general term for any hallucinogenic mushrooms used by Mexican Indians in pre-Columbian times and up to the present. While botanical interpretations of the word *teonanácatl* were originally based on Schultes's (13) paper, and referred to one single species of *Panaeolus*, we shall see subsequently that *teonanácatl* is not necessarily a single species, and that it is not - according to our present knowledge - probable that *Panaeolus* spp. are represented in the list of hallucinogenic mushrooms in Mexico.

Actually, the first correct interpretation of *teonanácatl* was published by this writer in 1951 (16, pp. 472, 506). This fact has not been mentioned in the current literature, although the genus *Psilocybe* as well as the species *Psilocybe cubensis* was mentioned by me in the place quoted. These indications were based on material collected by Dr. R. E. Schultes of Harvard University.

Schultes undoubtedly deposited the first botanically useful specimens of hallucinogenic mushrooms from Mexico in an American herbarium. These consisted of two collections, originally placed on one sheet in the Farlow Herbarium, but later separated by the present author (1941). One package containing *Panaeolus* was determined by D. H. Linder, then Curator of the Farlow Herbarium, as *Panaeolus campanulatus* var. *sphinctrinus*. If we disregard questions of nomenclature (the rules of botanical nomenclature necessitate a change in the name used by Linder, to read "*Panaeolus sphinctrinus* (Fr.) Quel."), we may say that Linder's determination is correct. Heim (3) came to the same conclusion. But even though the determination is correct for these specimens, it is obvious from certain data on the label of the collection[2] that there must have been some confusion of the *Panaeolus* with what later became known as *Psilocybe mexicana*, while on the other hand further inquiries show that *Panaeolus* is not one of the genera used by Mazatec Indians of the Huautla region for either religious or medical purposes.

---

1. Published out of order as excess pagination through financial assistance of the National Science Foundation and the University of Michigan Herbarium.
2. The label reads in part: "Springy meadows in rainy season. Huautla de Jiménez, Oaxaca, Mexico, July 27, 1938. Stem 1-2 mm diam., 10 cm high; hemispherical but often cuspidate; gills dark brown-black, whole plant coffee brown, black when dry. Mexican name nanacate. Indian name: she to (eruption of the earth); tso-ska (loco mushroom). Said to be poisonous in overdose of 50-60, but in moderate quantity it produces hilarity and general narcotic feeling of wellbeing for an hour. Excess doses said to produce permanent insanity. ..." It is now evident that "springy meadows" are the characteristic habitat of *Psilocybe mexicana*, and it is this species that is "cuspidate," never *Panoeolus sphinctrinus*; dark brown lamellae would be characteristic for the former, black ones for the latter. The name *she to* is a misspelling of *xi-tjo*, which is the general word for mushrooms and fails to identify the genus.

The other package, originally inserted with the first, remained unnamed in the Farlow Herbarium until this author in 1941 determined it as *Psilocybe cubensis* (Earle) Sing. (at that time still as "*Stropharia caerulescens* (Pat.) Sing. = *Stropharia cubensis* Earle"). Strangely enough, this second collection by Schultes contains a note in which the local name of the species is indicated[3] as *kee-sho*, which in Huautla does not refer to the species represented by the dried carpophores in the package, but to *Psilocybe caerulescens* Murr., as we shall see later. The specimens and data come from the not very accessible Mazatec village Huautla, the same village where the *Panaeolus sphinctrinus* had been collected, and where, later on, by Wasson, Heim, and Singer, *Psilocybe caerulescens* was likewise found (Fig. 1). If we assume that *Psilocybe mexicana* was originally confused with *Panaeolus sphinctrinus*, and *Psilocybe caerulescens* with *Psilocybe cubensis*, by Schultes's source of information, we already have all three important hallucinogenic mushrooms of the Mazatecs, or rather traces of them, in the first two records. These psilocybes will later be treated in more detail.

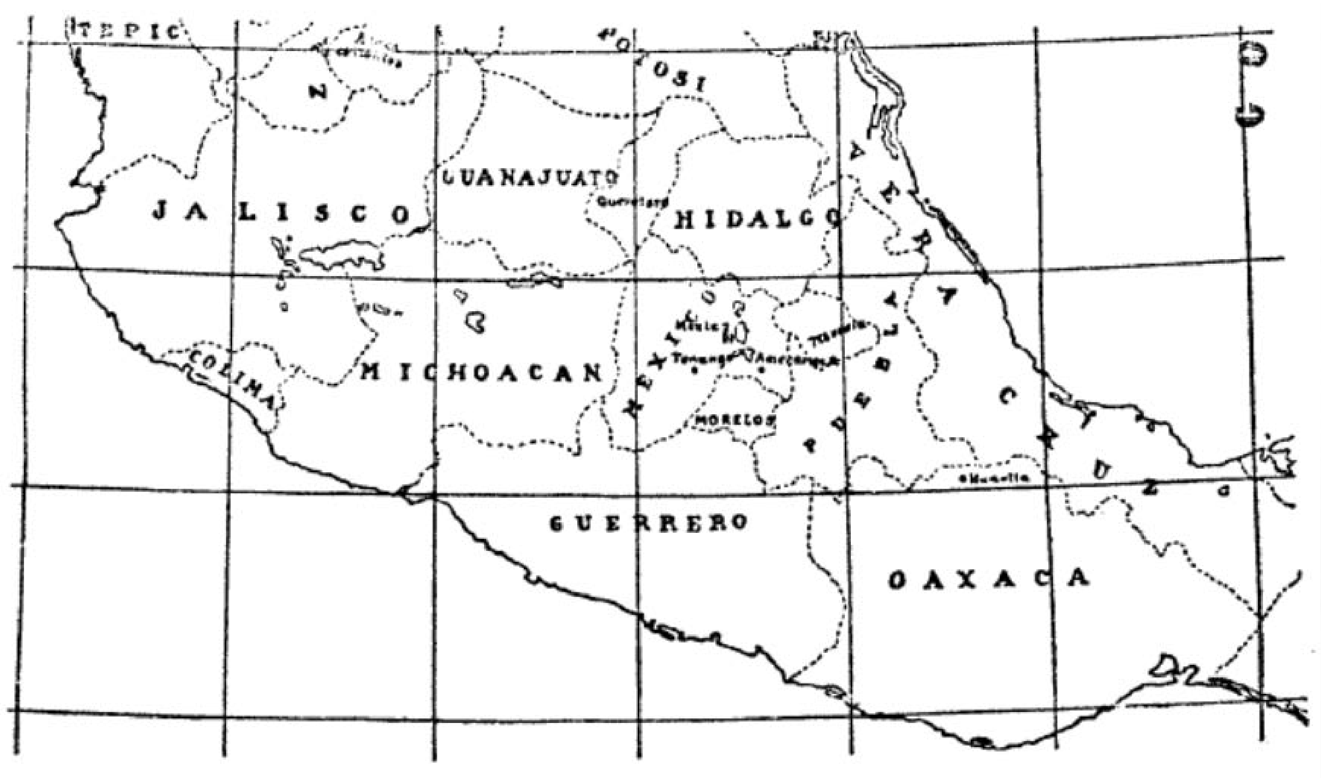

Fig. 1. Map of central and part of southern Mexico, between the 18th and 22nd parallels, showing Amecameca, Tenango, and Huautla in their respective states. 1:7,500,000.

This was the status of the mycological knowledge of *teonanácatl* when in 1952 Dr. Sam I. Stein became interested in the psychiatric implications of certain reports on the action of such dark-spored agarics as *Psilocybe* and *Panaeolus* (1, 2, 6, 9, 10, 11, 12, 13, 16). He then began to prepare the organization of a research program on fungus toxicology as related to neuropsychiatric problems. One of the first steps planned was the collection of dried material and cultures of the respective species, and of botanical observations made on the spot. These were not only to help in solving the basic problem from a biological point of view, but to produce sufficient knowledge to grow fruiting bodies of these species in the United States, or to grow mycelium in sufficient quantities to satisfy the demands of further investigations. The origin of these cultures had to be carpophores from the now classical village of Huautla de Jiménez, since obviously only a mushroom population known by previous tests and observations to be hallucinogenic should become the starting point of the production of carpophores destined to be the raw material for further experiments - particularly bio-assays and biochemical analyses - in the investigation on hallucinogens. This localization does not exclude further search for different species used in some remote valley of Mexico or Guatemala, or elsewhere.

---

[3] The label of this specimen reads: "Plantae Utiles Mexicanae. Oaxaca. Botanical Museum, Harvard University. Common name (Mexican) nanacate. Tribe: Mazatec. Indian name kee-sho. Habitat in freshets during rainy season. Locality Huautla de Jiménez, Oaxaca. Uses: From four to eight are eaten to produce a temporary narcotic state of hilarity. Said to be poisonous if taken in excess, causing permanent insanity. [Next follow descriptive data, illustrated by a drawing on the reverse side.] Coll. no. 349. Coll. Richard Evans Schultes, 27 July, 1938." Below Schultes's name that of Bias Pablo Reko is added (as co-collector). On a separate label, there is an annotation by Singer: "*Stropharia caerulescens* = *Psilocybe cubensis* (Earle) Sing.," and the Farlow label was made out correspondingly, although here the second and valid name was omitted. Thence resulted a later erroneous reinsertion in *Stropharia* when the herbarium material was shifted between 1949 and 1951, under W. L. White, curator.

The first author to publish data on chemical analysis and animal tests was Santesson (12), who unfortunately was handicapped by lack of thorough botanical study of the material he used, and by the application of inadequate chemical and experimental procedures. He had two samples, one "probably belonging to a *Panaeolus*", and the other supposed to be *Armillariella mellea* (although that was neither clear from the text nor at all probable). It is more likely that the material consisted of *Psilocybe mexicana* and *Psilocybe cubensis*, but it may conceivably have been a mixture of numerous elements. It was referred to as *teonanácatl*. Chemical reactions supposedly showed that no alkaloid was involved. According to the Fehling reaction, Santesson's material seemed to contain a glucoside as the active principle. Subcutaneous injections of 2.12 g and 1.57 g of the drug per kilogram body weight of *Rana temporaria* resulted in a "semi-narcosis" of the frogs, with a negative "turning test" (the classical inhibition effect of morphine on the rotation reflex of frogs).

At the time I reached Mexico - i.e., one year after Heim had accompanied the Wassons there - the former had already published three short communications (3, 4, 5) on specimens of Mexican species believed to be used in Indian ceremonies, and a preliminary article on his own observations. The name *Psilocybe mexicana* was then proposed for the first time, although not validly published before the second half of 1957. For what we consider to be *Psilocybe caerulescens* Murr., Heim proposed a new name, *Psilocybe mazatecorum*,[4] and having traveled to regions further south and northwest, he added a number of new entries on the list of species which collectively may be termed *teonanácatl*. Among them was *Psilocybe zapotecorum* Heim, from the Sierra Costera, and *Psilocybe aztecorum* Heim, from Popocatépetl. Fair to excellent illustrations of these species were provided by Heim for the Wassons' article (19) and in their book (20). In both of these latter publications as well as in other articles, ceremonies conducted by local *curanderos* (and a *curandera*) and experiences under the influence of hallucinogenic mushrooms were described by the Wassons and Roger Heim. No results of chemical analyses or animal tests have been published as this is written. Nevertheless, the attention given the mushrooms in the press has created - far beyond Mexico - an extraordinary interest and expectancy. Whether this attitude is justified by the research now in progress remains to be seen.

2. Field and culture work in 1957

My journey from Mexico City to the Mazatec country was undertaken in the company of two young Mexican botanists, M. A. Palacios, who worked as my assistant, and G. Guzmán H., an ardent student of agarics. There could not have been better traveling companions, or ones who better served the purpose of the trip.

We reached Huautla the first week of July and were there the guests of an Indian family. The head of the family, Isauro Nava García, an exceptionally intelligent and cooperative man who could express himself well in Spanish, and equally well spell the words of his native Mazateco, turned out to be a keen observer of fungi. He recognized easily and almost infallibly the different species of *Psilocybe*, knew where they could he found and when, and pointed out the interesting features of their respective habitats. He was of course completely familiar with the mushroom lore of his valley and had eaten hallucinogenic mushrooms before. Either he or his brother-in-law accompanied us in many of our collecting trips. Everything he said was checked by comparison with information obtained elsewhere. All the data obtained from him were corroborated with the exception of an opinion about the activity of a mushroom called "nèhe-je nèhe-je" (now known as *Psilocybe candidipes*), which was variously called inactive and poisonous. This, by the way, is the only species of the taxonomic group to which the hallucinogenic psilocybes belong that was not likewise reported by Wasson and Heim from the Mazatec region. On the other hand, the species said to be hallucinogenic and not belonging in the same taxonomic group as *Psilocybe cubensis*, *mexicana*, and *caerulescens* were not confirmed as hallucinogens by our own inquiries and observations. These unconfirmed data (3, 4, 16) refer to *Conocybe siligineoides* Heim, two species of *Panaeolus* (*Panaeolus sphinctrinus* and *Panaeolus fimicola* sensu Heim), and those psilocybes not reported to show any blue discoloration or stain (i.e., *Psilocybe cordispora* and *Psilocybe macrocystis*). I may add that there are a *Psathyrella* and copelandias from Santa Cruz which Guzmán, who collected them there, is inclined to think may be hallucinogenic. When we met Mr. Wasson in San Andrés near Huautla, he suggested that among these species the chances of finding real hallucinogens are rather good in *Conocybe*. So they are also in *Panaeolus* and related genera, since species of these have been shown to be poisonous or inebriating, and to be active in animal tests - *e.g.*, *Panaeolus venenosus* Murr. (9), which is apparently a synonym of *Panaeolus subbalteatus*, and species of the same genus or related genera determined in the past as *Panaeolus papilionaceus* and *Panaeolus* "*campanulatus*". Unfortunately, some of these determinations (1, 2, 6) may not be accurate and may just as well refer to other related genera (*Anellaria*, *Copelandia*), or at least to other species. We must insist, however, that the phenomena which belong in the class of "cerebral mycetisms" in the terminology of Ford (2) are not fully identical - although comparable - with the hallucinatory-euphoric and lasting effect described for the psilocybes. Aside from that we feel certain that *Panaeolus sphinctrinus* is not used as a drug by present-day Indians in Mexico.

---

[4] After having been advised by Dr. Alexander H. Smith of the probable identity of this fungus with Murrill's type of *Psilocybe caerulescens*, Heim changed the name to *Psilocybe caerulescens* var. *mazatecorum* Heim, because, as he explains, of the high variability of these fungi.

As for *Conocybe siligineoides* - which would be the only forest-inhabiting, or even xylophilous, species among those indicated by any author, it will be well to take into consideration a statement made to us by Isauro Nava. He said that there was, growing at a certain distant locality and not fruiting at the time of our visit, another hallucinogenic mushroom, as small as "pajaritos" (*Psilocybe mexicana*) and of the same shape and also staining blue, but differing in its habitat - wood in the forest rather than soil of meadows. Just such a species (*Psilocybe yungensis*) had been collected by me a year earlier in the ecologically very similar Bolivian Yungas, also a tropical-montane forest, and a similar but different one (*Psilocybe pelliculosa*) by Alexander H. Smith in the Pacific Coast area of the United States in coniferous forests of a temperate type. It is therefore quite possible that the missing forest-inhabiting hallucinogenic mushroom is not the species described by Heim as a *Conocybe*, but another representative of the section in which all the other hallucinogenic psilocybes belong.

How can such errors - if indeed errors they are - be explained? The growing demand for hallucinogenic mushrooms in the Huautla area has brought everybody, children and adults, many certainly much less expert than Isauro Nava, into the mushroom business. The younger generation of Indians tends to ridicule the use of mushrooms in ceremonies and is inadequately familiar with the characters of the mushrooms. Nevertheless, all these collect to fill the sudden demand at relatively high prices, and so inactive mushrooms are often mixed with active ones either by mistake or as conscious adulteration. I have witnessed the impurity and possible falsification of the product sold in Oaxaca, not easily discovered by anyone but a mycologist, especially if the material has been dried crudely for use between seasons. If substitution is discovered, the natural reaction of the seller is to claim that these different mushrooms are also used as hallucinogens.

As a result of the foregoing discussion, we may consider as established hallucinogens the following species of the Huautla region: (1) *Psilocybe cubensis* (Earle) Sing., (2) *Psilocybe caerulescens* Murr., and (3) *Psilocybe mexicana* Heim, and may add tentatively (4) *Psilocybe candidipes* Sing. & Smith (17).

By the end of July a further trip was organized by the National Autonomous University of Mexico, Institute of Biology, which took us by automobile to the region of Tenango del Valle (Fig. 1) southwest of Mexico City. A species of agaric is prescribed there by a "*curandera*" of a small village above Tenango and at times sold in the market at Tenango; it is currently collected by many local inhabitants of the region for storage, to have ready in case of illness, especially stomach troubles. The specimens come from a place called Piedras Blancas on the slopes of Cerro de Toluca. From our investigation on good specimens obtained at Piedras Blancas, and from observations on pure cultures made from them, we believe that they are an independent species, and not a variety of any known species, as suggested by Heim (4). We add therefore (5) *Psilocybe muliercula* Sing. & Smith (17), "mujercitas."

A similar trip, a week earlier, was made to San Pedro de Nexapa near Amecameca (Fig. 1) in the Distrito Federal and at the borderline with Puebla. This trip in search of the species previously described (from purchased specimens) by Heim as *Psilocybe aztecorum* yielded no specimens, and we had to rely for the moment on material which did not produce cultures. The information about the use of the mushroom was, however, obtained from the informant in Nexapa interviewed by Heim, and the exact habitat of Heim's *Psilocybe aztecorum* was carefully studied. Since the fruiting bodies appear only later in the year, G. Guzmán followed this exploratory trip with a second one in September, from which good specimens were collected at their natural habitat, and cultures were taken from the lamellae of these. The use made of *Psilocybe aztecorum* seems to be exactly the same as that made of *Psilocybe muliercula*. Consequently we list (6) *Psilocybe aztecorum* Heim.

All six species enumerated have a number of important characters in common - first of all the diagnostic characters of the genus as defined by Singer (16). They are devoid of chrysocystidia, do not show a glutinous or viscid veil on the stipe, and have the stipe centrally attached. The spore print is fuscous sepia or dark purple brown (often more deep lilac when quite fresh), as is usual in the entire subfamily Stropharioideae of which *Psilocybe*is a genus. The spores are smooth and have a germ pore. Some species have rather strongly longitudinally compressed spores, although with few exceptions the compression is not strong enough to be the same as that observed in the true deconicas,[5] and the spore size is variable from species to species (4-17 µ long). The upper layer of the pileus is a cutis, with a more or less individualized epicutis which often takes the appearance of a pellicle. A veil is present in all these species but the extent of development of the veil in adult specimens varies according to, and to a certain degree even within, the species. Some species have a persistent although never furrowed ("lamellar") thin repand annular veil. *Psilocybe candidipes* has an abundant veil development, but the annulus is narrow and not persistent. *Psilocybe caerulescens*, *Psilocybe aztecorum*, and some other species still have a well developed veil, but it is obliterated in age and never forms an annulus. In *Psilocybe mexicana*, on the other hand, is reached the extreme situation in this group, where the veil consists merely of a number of fine silky hyaline fibrils connecting the apex of the stipe with the margin of the pileus when the carpophore is young, collapsing on the stipe to form appressed scattered silky fibrils which disappear completely in age.

Aside from the generic characters indicated above, all the species that enter our list of Mexican hallucinogens have a very interesting and striking chemical character, one that is very constant in young and fresh material, but becomes lost in old and dried material, especially where the climatic conditions provide relatively high temperature. When the fruiting bodies are scratched or handled, or dried out, they stain blue or (in superposition on a yellowish pigment) green. This is apparently an enzymatic oxidation or autoxidation which may be comparable with that of *Russula* sect. *Nigricantinae* (where tyrosinase is the enzyme active in producing through the oxidation of tyrosine a melanin-like blue or pink and eventually blackening substance), or of the bluing boletes like *Boletus luridus* (with boletol, the pigment resulting being blue). The reaction is certainly identical with that observed in related genera of *Agaricales* like *Copelandia* and in certain species of *Pholiotina*. Some reagents such as guaiac solution accelerate this reaction in the few cases where I could make the test, but the action of guaiac is said to be nil by other authors in other cases. However, a chemical character which accompanies the bluing phenomenon is that of metol, which gives a constant strongly positive reaction with the context of the stipe in the bluing psilocybes, becoming deep purple after a few minutes (Singer 15, 16). Furthermore, it appears that the odor and taste of the whole group are sometimes distinctive: the odor of fresh carpophores is that of fresh flour or cucumber, or more rarely absent, or raphanaceous; while the taste is either hardly distinctive or more or less astringent or unpleasant. Heim (5) also indicates, among the characteristics of the hallucinogenic group, the fact that the spores show a light ocher pigmentation. It should not he denied that a very large number of *Strophariaceae* - Stropharioideae may show a light ocher color when seen under moderate magnifications in strong light or when not fully mature. However, my findings, corroborated by other observers, do not support the generalization that this particular light ocher color is characteristic for the Mexican hallucinogenic psilocybes or for the section of *Psilocybe* in which they belong.

Ecologically, however, all these species (even though not all the species which taxonomically belong with them) are adapted to conditions brought about by either cattle raising or agriculture, or else by natural but violent and profound disturbances of the equilibrium of the soil flora. Although not one of the species is carbonicolous or ruderal, the specific ecology of the Mexican species has apparently much in common with the ecology of anthracophilous and ruderal agarics.

---

[5] Dr. A. H. Smith thinks that species with strongly lentiform rhombic spores of small size should not be generically separated from *Psilocybe*. It is possible, and even probable, that the study of a large number of species not yet analyzed will corroborate this opinion when the genus is finally monographed.

With the characteristics indicated above, the hallucinogenic mushrooms enter quite naturally a taxonomic subdivision proposed by this author in 1948 (15) as the section *Caerulescentes* Sing., with *Psilocybe cubensis* as the type species. This section consisted even then of one annulate and several exannulate species. The fact that both annulate and non-annulate species enter the section now, having in common, in addition to their anatomical and chemical characters, the physiological activity referred to as "hallucinatory" (in reality a complex action) or as provoking cerebral mycetisms, tends to show that the section *Caerulescentes* is a natural one, whatever weight conservative authors may still give the veil characters in other groups of agarics. The fact that *Psilocybe cubensis* is among the hallucinogenic mushrooms will thus serve as an additional argument in favor of its transfer from *Stropharia* to *Psilocybe* (Singer, 15) where its real affinities are. Why, in view of the considerable evidence in favor of its transfer, Heim (3) retains the species in *Stropharia*, with the cryptic remark "ils [*i.e.*, *Psilocybe cubensis* and synonyms or related species] restent cependant apparentés avec *Stropharia squamosa* Fr. ex Pers.,"[6] is not recorded.

The type of vegetation in which hallucinogenic psilocybes occur is not uniform. The vegetation found in the Huautla region (and apparently in other areas where hallucinogenic mushrooms were observed in Oaxaca) is markedly different from that in Mexico and Puebla, further north and higher up. The Oaxaca localities, or, more properly, the Huautla region, can be characterized as transitional between tropical montane and temperate montane, the tropical montane zone being immediately adjacent in the ravines below 1500 m and the temperate montane zone in the alder forests above 2000 m altitude. The tropical montane region adjoins farther down and farther east the more truly tropical rain forests, as seen in the lower-level forests of Santa Cruz - near Jalapa, for example, where Murrill collected - and the transition zone characteristic of the localities where hallucinogenic psilocybes abound may well be likened to the South American fog- or cloud-forest. It differs, however, in at least one important point: the Mexican forests are rich in trees belonging to the order Fagales, especially in evergreen oaks, which determine the mycoflora and make the presence of abundant ectotrophic mycorrhiza possible. In many places in this transitional zone or modified cloud forest limestone crops out, and a high percentage of calcium may he expected in soil samples, especially from our *Psilocybe mexicana* habitats. The rainy season extends over the entire summer, and the rains are extraordinarily abundant and almost continuous for weeks in certain times of the year.[7]

The often torrential rainfall, in combination with the quality of the soil and the steepness of the mountain sides, creates a situation quite comparable to that in the upper Yungas in South America. Here as there frequent earth and stone avalanches cover the vegetation and bring the subsoil and deeper layers to the surface. This process is particularly accelerated by the methods of agriculture and will be speeded further by roadbuilding.

---

6. This is a species so different from both typical *Strophariae* like *Stropharia aeruginosa* and typical psilocybes like *Psilocybe semilanceata* (because of the combination of characters of the cystidia and the hypodermial and hymenophoral trama-structure) that it has been pointed out by Kühner (7) as anatomically closer to *Hypholoma*. For that reason it was transferred by Singer (16) to the genus *Naematoloma* (= *Hypholoma* sensu Kühner). *Stropharia squamosa*, or better *Naematoloma squamosum*, differs sharply from both typical stropharias and typical psilocybes in habitat requirements also, being, like so many naematolomas, a wood-inhabiting species; this ecological character of course also occurs in other genera, and in itself cannot be considered to be decisive.
7. The climate of this transitional-vegetation area where all our Huautla material came from varies between limits such as those quoted for the two extreme localities Huauchinango (Puebla) and Jalapa (Veracruz), the one being more similar to the upper limit of the Huautla zone, the other being at the lower level of the tropical montane zone. In these two comparable localities temperature records (°F) are:

Locality	Lowest minimum	Highest maximum	Ave. coldest month	Ave. hottest month	Ann. ave.
Huauchinango	25	104	50	66	60
Jalapa	36	99	58	68	64

The observed precipitation (inches) as rain:

Locality	Ave. ann. precip.	Ave. driest month	Ave. wettest month
Huauchinango	87.4	1.9 (Febr.)	15.6 (Sept.)
Jalapa	62	1.8 (Dec.)	11.6 (June)

The data are based on Vivó and Gomez, Climatologia de México, Inst. Panamer. Geol. e Historia publ. 19, México, 1946, quoted from Miranda & Sharp (8).

The natural forest, interspersed with small pastures, fields (mostly sugar cane, some corn), and now an increasing number of coffee plantations, is partly preserved, and contains, aside from tropical and endemic elements and the species of *Quercus* already mentioned, some elements in common with the subtropical and temperate forests of the southeastern United States from North Carolina to Florida. Such elements among the trees are *Liquidambar styraciflua*, among the fungi *Hygrophoropsis tapinia* Sing., and among the species referable to *teonanácatl*, *Psilocybe caerulescens* Murr. At the same time one observes numerous species of *Marasmius* which prove the tropical relations of this region. All together, the mycoflora of this transition region is just as heterogeneous as the tree flora. As one ascends, entering the *Alnus* stands at about 2000 m, just above the transition zone, one might expect to encounter a fungous flora with even more distinctly northern links. This is not the case. The mycorrhizal partner of the alder is the same as that found at the south tip of the alder area in South America, a bolete, *Gyrodon monticola* Sing., absent from the United States and Canada.

The hallucinogenic psilocybes fruit during early (spring) rains and until fall. *Psilocybe cubensis* seems to be one of the earliest-fruiting species; I have observed fruiting in spring in Florida. But it continues producing fruiting bodies during the entire season. The habitats of all the species in the Huautla region are characteristic. *Psilocybe cubensis* is dung-inhabiting. It occurs on pastures where cattle have grazed, or among sugar cane residues, but usually where the substratum has at least been mixed with cow dung. Sugar cane mulch, but without dung, is also a habitat of *Psilocybe caerulescens*, but it grows just as often on other plant material or around living culms of *Saccharum* on the earth of the fields. The same situation can sometimes be observed of *Psilocybe mexicana*. However, *Psilocybe caerulescens* grows mainly in shaded places in plantations or shaded fields, while *Psilocybe mexicana* prefers sunny open fields and pastures. *Psilocybe caerulescens*, according to the statements of the Mazatec Indians whom we consulted, regularly inhabits the surface of old landslides, two or more years after the landslide has occurred. We found this observation correct as far as the Huautla stations are concerned, and the description of the type locality in Alabama coincides in type of soil with that seen by us. On the other hand, the open pasture land on which *Psilocybe mexicana* is found is probably mostly man-made, or at least is maintained in its present condition by the grazing of animals. *Psilocybe candidipes* grows characteristically on the cleared surface of the earth among tree leaves fallen to the ground under *Coffea* and its shade trees (especially *Inga*). According to our Indian informants, especially Isauro Nava and his neighbors and relatives, and our own observations in this region, *Psilocybe candidipes* always occurs near the habitats of *Psilocybe caerulescens* and when found serves as an indication that *Psilocybe caerulescens* is not far.

The Mazateco name for *Psilocybe mexicana* is according to Isauro Nava a word he wrote for us and that sounded like the Spanish pronunciation of *di-nizé*, and which means a bird (diminutive), supposedly, always according to Isauro, because it makes you sing happily like a bird.[8] For *Psilocybe caerulescens* the indigenous name noted is *di-ki-sho* (or what sounded like this); it was explained that *di* stands again for the diminutive and *ki-sho* means landslide, this name being related to the habitat of the fungus.[9] For *Psilocybe cubensis* we were given two native names, one being San Isidro, which is self-pronouncing, and the other what sounds like and was transcribed as *di-shi-tjo-le-ra-ja*, which means steer mushroom in a diminutive form.[10] It is quite obvious that San Isidro stands for an earlier heathen god who was supposed to speak through the mushroom. It is also obvious that the relation of the fungus with the steer is again that of habitat, since in the Huautla region the species grows mostly on cattle dung. *Psilocybe candidipes* is referred to as *'nchè-jè 'nchè-jè* (Isauro's spelling).[11]

---

[8] Mr. George M. Cowan, a student of the Mazateco language, was kind enough to offer the following comments: "We use what we choose to call a practical orthography in all published materials used by Mazatecs now. This is simply a phonetic alphabet adapted as far as possible to the Standard Spanish alphabet. Tone is significant in Mazateco; the numbers $^{1\ 2\ 3\ 4}$ represent relative pitch of the syllables; ^{1} represents the highest, ^{4} the lowest level. [The symbol] (') cannot be transcribed in English orthography and is not heard by the untrained ear; it is sort of a glottal catch preceding the following sound." The correct phonetic spelling of *di-nizé* is, according to Mr. Cowan, 'nti^{1}-ni^{4}-se^{3}; it is pronounced ndee^{1} nee^{4} say^{8}; nti = ndee means an affectionately regarded object (referring to the mushroom) and ni-se, bird.

[9] Mr. Cowan's comments indicate that here as in the case of *Psilocybe mexicana* Isauro's names are current abbreviated words, omitting between the '*nti* and the *ki-sho*, the general term for mushrooms, *xi*^{3}*-tjo*^{3} ("which comes out," presumably of the earth), so that the full name of *Psilocybe mexicana* would be '*nti*^{1}*-xi*^{3}*-tjo*^{3}*-ni*^{4}*-se*^{3}, and for *Psilocybe caerulescens*: '*nti*^{1}*-xi*^{3}*-tjo*^{3}*-qui*^{3}*-xo*^{1}, pronounced *ndee*^{1}*-shree*^{3}*-t(h)oe*^{3}*-kee*^{3}*-shro*^{1}, meaning dear little thing that comes out of the earth of a landslide. The *x* is a sound as if English sh and r were pronounced at the same time; j and qu are pronounced as in Spanish, *i.e.* as a more aspirated *h* and a *k* respectively. "Tsami kishu" given by J. B. Johnson (quoted from Schultes, 13) evidently refers to this same species.

[10] G. M. Cowan spells this '*nti*^{1}*-xi*^{3}*-tjo*^{3}*-le*^{4}*-nčha*^{4}*-ja*^{4}, pronounced *ndee*^{1}*-shree*^{3}*-t(h)oe*^{3}*-lay*^{4}*-njra*^{4}*-ha*^{4} (meaning as above: the dear little thing that comes out pertaining to the steer or ox). The pronunciation of čh is described as a sound similar to English *j* (in judge) and *r* (in run) if pronounced simultaneously.

The two montane-temperate to subalpine-frigid habitats in the *pinares* (pine woods region) of the mountains nearer Mexico City mentioned above as harboring two hallucinogenic psilocybes (*Psilocybe aztecorum* and *Psilocybe muliercula*) differ from the transition forest of the Mazatec region not only climatically but likewise in the type of vegetation. The mushrooms do not, apparently, depend in any way on the detritus or the presence of living roots of the characteristic pines (*Pinus hartwegii* with *Psilocybe aztecorum*, *Pinus pseudostrobus* with *Psilocybe muliercula*). Neither do they live on agricultural land or dung, but directly on the earth, naked earth on the banks of mountain streams with occasional salt outcroppings, following the ravines around 3000 m elevation, or else (*Psilocybe aztecorum*) among grasses and (rosaceous) herbs in openings, often on the slopes of steep ravines even higher up (between 3300 and 3700 m altitude). The subalpine pine woods are here beginning to thin out and approach the absolute timber line (at about 4000 m). The psilocybes are accompanied by those mycorrhizal Basidiomycetes which make the survival of these pines possible at such an altitude, especially *Amanita inaurata* Secr., various species of *Lactarius*, and *Suillus* aff. *brevipes* (Peck) Sing. Non-mycorrhizal Basidiomycetes of this vegetation are *Phlogiotis helvelloides* (Fr.) Martin, *Tubaria* sp. (on *Pentstemon barbatus*), and *Laccaria* aff. *laccata* (Scop. ex Fr.) Berk. & Br. Among the Ascomycetes are *Cordyceps capitata* (Fr.) Link (on *Elaphomyces*) and *Hypomyces lactifluorum* (on *Russula delica*), the former often collected as a remedy for various diseases but doubtfully hallucinogenic,[12] the latter sold in the food markets. In the Piedras Blancas region on Cerro Toluca the presence of *Amanita calyptratoides* Atk., a western North American species, is remarkable; the southeastern race of *Amanita muscaria*, also a hallucinogenic mushroom of a sort, and almost constantly accompanying pine mycorrhiza, is common in the neighborhood of the psilocybes, but has never been mentioned as a locally accepted drug.

While the substratum of both *Psilocybe aztecorum* and *Psilocybe muliercula* is apparently comparable to that of *Psilocybe caerulescens* (more or less unstable or shifting bare soil), the climatic conditions and the surrounding vegetation are very different in this region from the *Psilocybe* habitats in Oaxaca. There is frequent freezing in the altitudes indicated, and the precipitation is not so abundant here as in the Mazatec country. During the summer-fall rainy season, precipitation is heavy enough to maintain a relatively rich flora of large fleshy Basidiomycetes reminiscent of that further north in Mexico and in the United States. This, obviously, is possible only because of the relatively lower temperatures, even in summer, whereby evaporation is kept at a minimum.

Psilocybe aztecorum is known as *niños del agua* (Spanish: children of the water; this is apparently an allusion to their habitat along the ravines). *Psilocybe muliercula* from Piedras Blancas is also known as "niños," but as such it is only one of the elements referred to by the more general term niños which includes "mujercitas" and "hombrecitos" (little women and little men). Only the "mujercitas" are agarics (*Psilocybe muliercula*); the "hombrecitos" are *Cordyceps capitata* (Fr.) Link (det. Mains). There is an obvious misinterpretation of these names in the literature. Although "mujercitas" are correctly interpreted as *Psilocybe*, the term has been thought to refer to a variety of *Psilocybe mexicana*. Dr. Herrera and the author, however, found the difference in external appearance and habitat constant enough to separate the "mujercitas" from *Psilocybe mexicana*, inasmuch as in all natural habitats of the two species the spore size is consistently different. On the other hand, "hombrecitos" have been interpreted as merely smaller individuals of *Psilocybe mexicana* var., or, since hallucinatory mushrooms in Mexico are always given in pairs, the complementary individuals - in other words, part of the same drug. Our own interpretation has been reconfirmed several times, and it is also obviously the logical interpretation, since the allusion to the shape of the respective fruiting bodies is self-explanatory, and the terms lose all descriptive significance if Heim's and Wasson's explanations are accepted.

---

[11] Mr. Cowan, who had a special interview about this new species with Isauro and friends, explains that this means, as Isauro had already told us, "a signal of," in reference to the other hallucinogenic mushrooms, particularly *Psilocybe caerulescens*, which will appear here or nearby later. The correct spelling is *nche*^{4} *je*^{4}, pronounced in English like njre^4-he^4.

[12] It is remarkable that another species of the same family, *Cordyceps sinensis*, growing on insects, is widely used as a medicine in China, while still another species of the Hypocreaceae, *Claviceps purpurea*, ergot, is the source of several alkaloids which have only recently been studied thoroughly. In view of this, it is very probable that the Mexican medicinal hypocreaceous species would be well worth a special investigation, particularly from the biochemical point of view.

It is interesting to note that not only are the conditions under which the respective fungi develop widely different, but the use made of the mushrooms is likewise different, in the main hallucinogen-producing states of Mexico visited by me. The Nahua Indians, according to the data obtained by us in discussions with inhabitants of San Pedro de Nexapa and Tenango del Valle as well as the mountains near these villages, do not talk about the hallucinogenic effect of the mushrooms, but volunteer information merely on their healing qualities. In these villages, the use is strictly a matter of religious healing, the business of the *curandero* or *curandera*. Permission has to be granted by God in the *curandero's* dream before the drug can be employed safely. On the other hand, the Mazatecs talk freely about the hallucinogenic and euphoric effects of these mushrooms, and eat them for precisely that effect. The religious healing ceremonies of the Mazatecs are also directed by *curanderos*, but more emphasis is given to the revelations obtained by the intoxicated persons, so that the use made of the mushroom in Huautla is at least partly divinatory rather than directly medical. Whether this corresponds to any difference in the chemicals present in the respective species, or merely to ethnological factors, cannot be stated at present. At any rate, the Mazatecs seem to have preserved more of the original Aztec lore about *teonanácatl* than the people living now in Aztec country, who are at least in part the direct descendants of the Aztecs. It is of course possible that the secretive and exclusive use the Nahuas make of their "niños" is a result of more complete repression and conversion in the early times of the Spanish rule, when the Oaxaca Indians of the Sierras were practically left to their own devices.

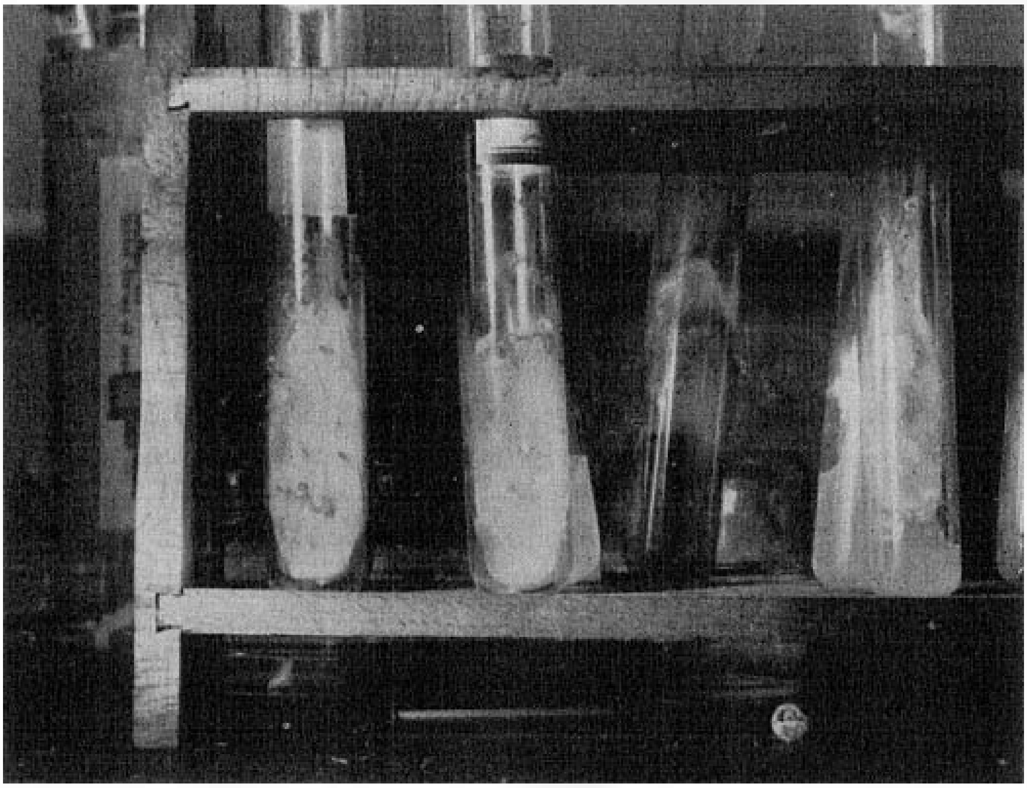

Fig. 2. *Psilocybe cubensis*. Stringy mycelium (upper portion of slant in tube at extreme left) and primordia. Phot. R. Singer.

From all the species mentioned above, including also *Panaeolus sphinctrinus*, both tissue cultures and spore germinations were obtained. The tissue fragments grew well at the room temperatures of Mexico City in July, some even better at 27-29°C, and better on malt-extract agar and Kauffman's (modified) medium than on potato-dextrose agar. These were the first pure cultures obtained directly from fruiting bodies at their classical habitats. Subcultures have been deposited at the Instituto Politécnico and the Instituto de Biologia of the University of Mexico, at the Department of Botany of the University of Michigan, The New York Botanical Garden, and the Phytopathology Laboratory of the Ministerio de Agricultura y Ganadería in Buenos Aires, all in personal care of responsible scientists for specified further research on these organisms. For the sake of comparison, isolations were also made from North American spore prints of *Psilocybe caerulipes* (Peck) Sacc. (northern Michigan), also belonging to the section *Caerulescentes*, and from *Copelandia caerulescens* (Berk & Br.) Sing.

Panaeolus sphinctrinus, *Psilocybe cubensis*, *Psilocybe caerulescens*, *Psilocybe candidipes*, and *Psilocybe mexicana* were checked by Dr. W. J. Robbins for antibiotic activity. None was evidenced against *Staphylococcus aureus* or *Escherichia coli*, and the action against *Mycobacterium smegma* was slight.

Psilocybe cubensis has been observed to form a stringy mycelium in malt-agar test tubes. Mycelium of this species, more than that of other species studied in pure culture, has a tendency, greater at lower temperatures than at higher ones, to turn blue in culture. *Psilocybe cubensis* also tends to produce most easily what might be termed white rhizomorphs in the stringy portions of the mycelium, and a large number of small fruiting bodies on the agar (Fig. 2). These carpophores or primordia do not always attain full size during later development, and often fail to mature; they tend to turn blue without being handled. The agar cultures of *Psilocybe mexicana* have a tendency to turn deep brown in contact with the mycelium (Fig. 3). On partially drying out they also frequently produce normal fruiting bodies. On the other hand, *Psilocybe caerulescens* under the conditions in which it was kept in the laboratory did not form white rhizomorphs or fruiting bodies in pure culture, and the mycelium merely colors the medium light brown (Fig. 4). In Czapek with 1% sucrose and vitamins, *Psilocybe caerulescens* produced aerial mycelium which broke down into "oidia" (mycelial fragments often referred to as arthrospores), observed for the first time by Dr. R. Ames. The mycelium of the *Panaeolus* remains pure white and fluffy without distinct discolorations, rhizomorphs, or fructifications. The same is true for other psilocybes except *Psilocybe muliercula*, which tends to form a slightly brownish aerial mycelium.

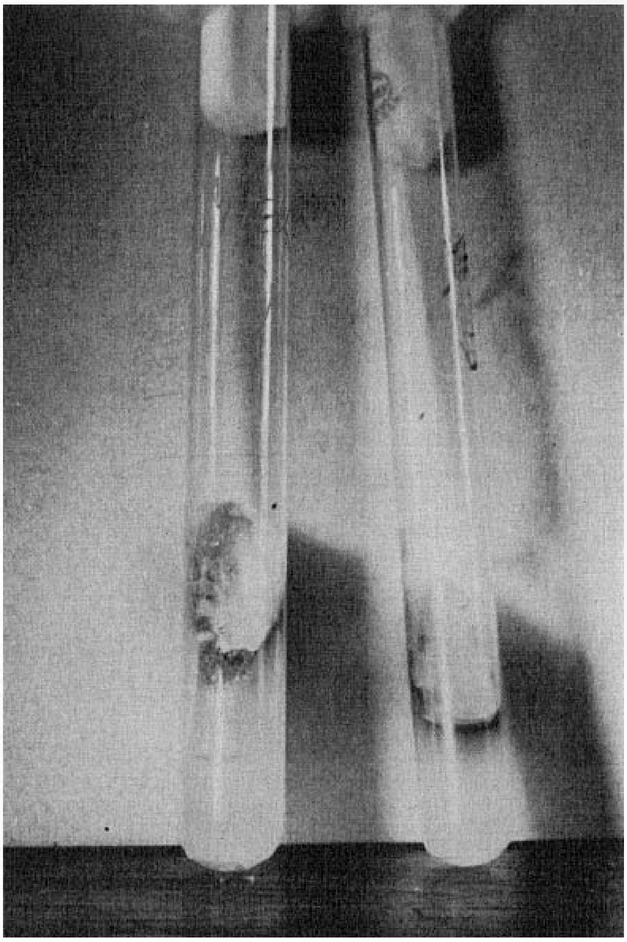

Fig. 3. *Psilocybe mexicana*, showing the dark discoloration of the medium beneath the whitish mycelium in both test tubes. Phot. R. Singer.

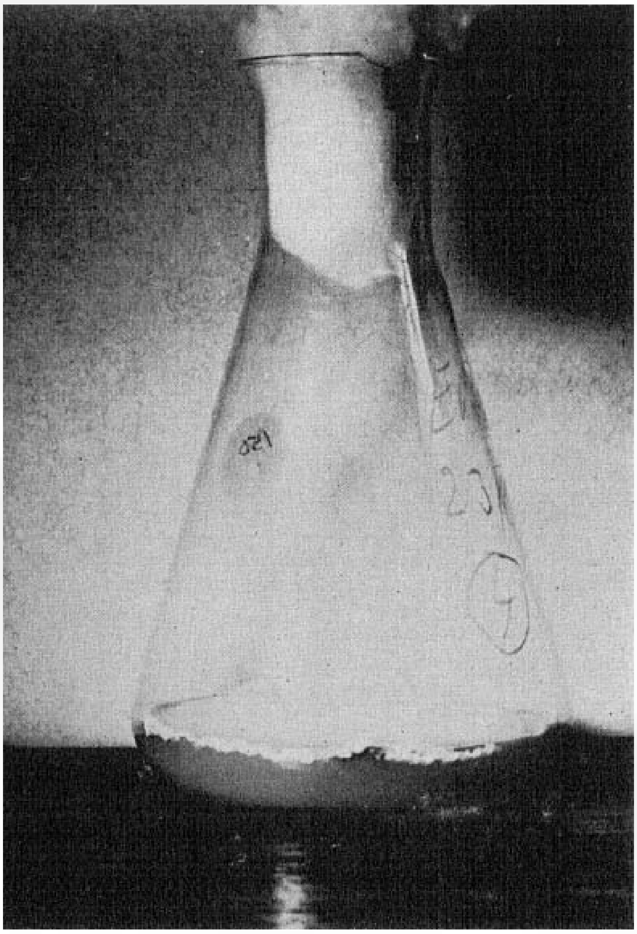

Fig. 4. *Psilocybe caerulescens*. Typical mycelium culture in Erlenmeyer flask. Phot. R. Singer.

Panaeolus sphinctrinus (Fig. 5) and other species of *Panaeolus* grow in mushroom-house conditions as well as or better than *Agaricus bisporus* (Lange) Sing., the cultivated mushroom. The psilocybes were also grown not only under laboratory conditions in large glass containers (Fig. 6), where some produce large fleshy fructifications, but also in greenhouse conditions (Fig. 6) on compost trays, where the method used by commercial mushroom growers had to be considerably modified.

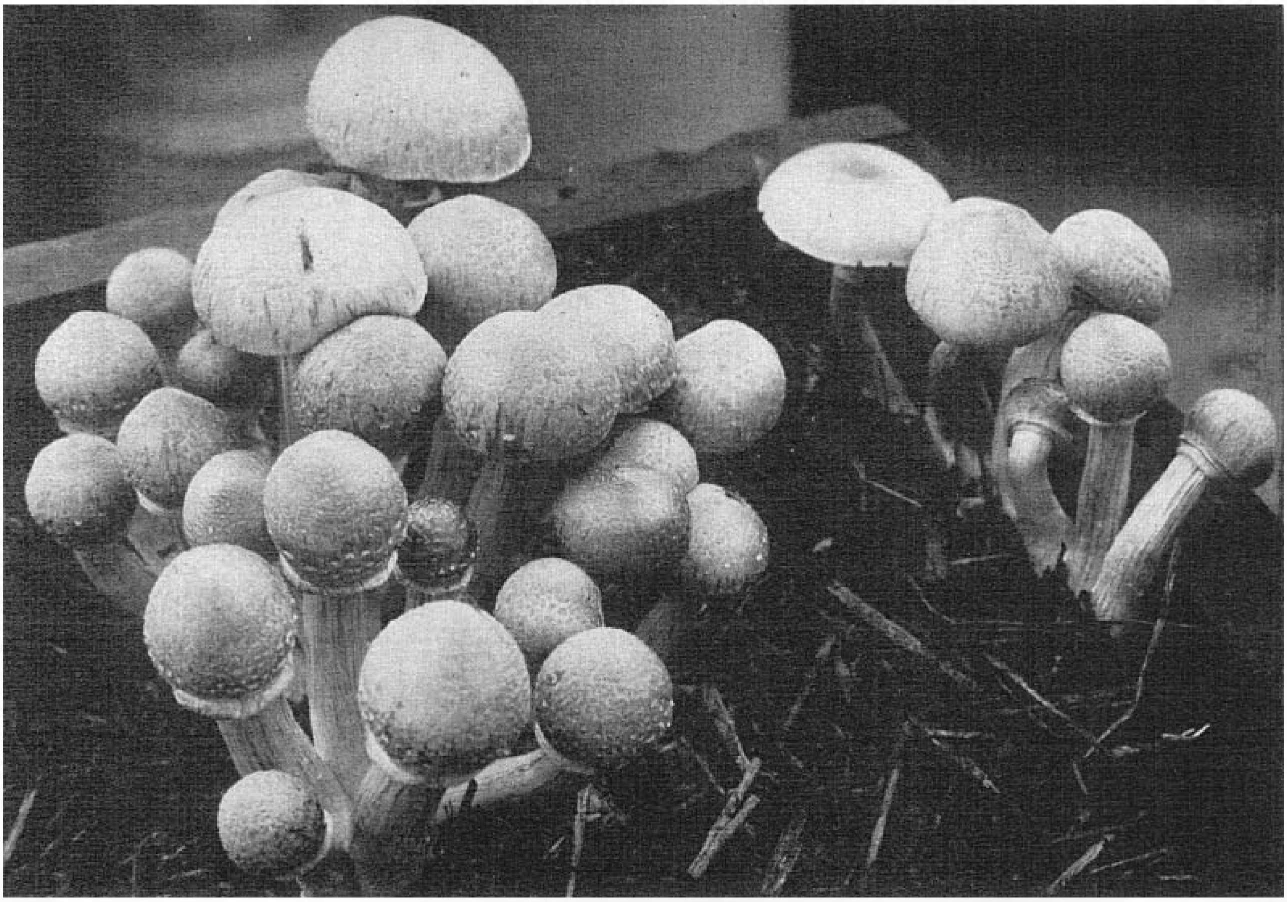

Fig. 6. *Psilocybe cubensis*. Greenhouse culture on uncased tray with compost, slightly reduced. Photog. Serv. Penn. State Univ., courtesy Dr. L. R. Kneebone.

Acknowledgments

It is a pleasant duty to thank the University of Tucumán and the Instituto Miguel Lillo for having granted the necessary leave to carry out the present investigations; the authorities of the Instituto de Biologia (University of Mexico), and especially Dr. R. Llamas, for having authorized the collaboration of the staff and the use of its facilities; and Miss Martha Zentena Zevalla and Dr. Teófilo Herrera for help in the preparation of media and the organization of field trips. Both went beyond purely scientific collaboration by trying successfully to make my stay in Mexico as pleasant as possible. Mrs. Ana Mas Gomez of the American Embassy was kind and patient in obtaining all the permits for the collection, export, and import into the United States of America of the cultures, spore prints, and dried material, and offered many other courtesies. Miss Dorothy Parker of the Rockefeller Foundation in Mexico was very helpful in establishing valuable contacts during the Mexican phase of the work. Mr. G. M. Cowan, Summer Institute of Linguistics, offered generous help in the interpretation of my notes on Mazateco fungus names.

This cooperation continued in the United States. Dr. K. L. Jones, Head of the Department of Botany, University of Michigan, and Dr. E. B. Mains, Director of the University Herbarium, made it possible for me to carry out part of the research in Ann Arbor. Dr. A. S. Sussman was particularly kind in supplying the necessary equipment and in providing valuable advice to me and my collaborators in the Department of Botany. He as well as Dr. A. H. Smith offered interest and encouragement.

It should also be stated that had it not been for the consistent initiative and the financial backing of the Bertram and Roberta Stein Neuropsychiatric Research Program, Inc., of Chicago, the present work would not have been possible, and the investigations now in progress elsewhere would have had no chance of realization. I am particularly indebted to Dr. Sam I. Stein, Executive Medical Director of the organization.

Part II.
A taxonomic monograph of psilocybe, section caerulescentes[1]

by

Rolf Singer and Alexander H. Smith

As has been shown by Rolf Singer in Part I of these studies, it may be accepted as probable that the majority of the hallucinogenic mushrooms of Mexico belong to the section *Caerulescentes* of the genus *Psilocybe*. It is not yet known whether all species of the section possess hallucinatory properties, but it is probable that all or at least many of them are hallucinogenic or poisonous, causing cerebral mycetism with or without other symptoms. At all events, a critical taxonomic account of the species in this section is highly desirable to facilitate a biochemical survey of the group. This contribution is a part of two major projects, first the research on hallucinogenic mushrooms carried out by the Bertram and Roberta Stein Neuropsychiatric Research Program Inc., Chicago, Illinois, and second, a monograph of the North American species of *Psilocybe* now in preparation by A. H. Smith.

We wish to express our thanks to the curators of the following institutions from which we have received material for study: Kew Herbarium (K), Dr. G. Taylor, Director, and Dr. R. W. G. Dennis, curator; Farlow Herbarium (FH), Dr. I. M. Lamb; New York Botanical Garden (NY), Dr. D. P. Rogers. Our own collections and those obtained from correspondents are on deposit at the Instituto Miguel Lillo (LIL), Tucumán, Argentina, and at the Herbarium of the University of Michigan (MICH). Valuable data were obtained for us by G. Guzmán, Mexico D.F.

The color terms used in the descriptions were taken from R. Ridgway, Color Standards and Color Nomenclature, Washington, D.C., 1912, and Maerz and Paul, A Dictionary of Color, 1st edition, McGraw-Hill, New York, 1935. Those from Ridgway are within quotation marks and those from Maerz and Paul are underlined.

In giving the measurements of spores the length is given first and the width second, but if the spore is somewhat compressed and broader than deep, the width is given following the length and the depth (i.e. breadth in side view or profile) is given last - for example, 8-11 x 6-7 x 5-6 µ. Measurements of the cystidia (including cheilocystidia) give the length first, the width of the broadest part next (usually the diameter of the basal or central enlargement), then follows the diameter of the "neck" (thinned apical portion) or the narrowed part above the mid-portion, unless the apex is described separately.

The cultural characters as far as now available are not part of the descriptions provided in this monograph since the cultures were described by Singer in Part I. Nevertheless, some of the data provide interesting and even diagnostic characteristics of certain species.

This work has been supported by the Bertram and Roberta Stein Neuropsychiatric Research Program Inc., Chicago, Illinois, The Faculty Research Fund of the University of Michigan and the National Science Foundation.

Psilocybe sect. Caerulescentes Sing., Sydowia 2: 37. 1948.

Pileus white or pigmented, slightly lubricous to almost glutinous in wet weather, pellicle often separable; lamellae ascending or horizontal, usually adnate, in some species subdecurrent, in others sinuate-adnexed, edges pallid, faces pallid to brownish, becoming purple brown from the spores; stipe slender to fairly robust, strongly purple with metol (p-metylaminophenol-sulfate), usually bluing with guaiac solution, typically bluing when wounded or blue color becoming evident on surfaces or mycelium under certain conditions of growth or in age or on drying.

---

[1] Papers from the University of Michigan Herbarium and Department of Botany no. 1074, University of Michigan, Ann. Arbor, Mich.

Spores purple fuscous to lilac in fresh deposits or in water-mounts under the microscope, *after dehydration and then mounting in KOH* becoming dark yellowish brown, terete to laterally compressed and variable in shape from species to species, smooth, wall complex, apical pore distinct and typically causing the apex to appear truncate; basidia typically 4-spored, pleurocystidia present or absent but if present not as chrysocystidia (species with chrysocystidia excluded from *Psilocybe* by definition); cheilocystidia abundant and often causing the gill edge to be heteromorphous (completely sterile and sterile elements different from those of gill face), or nearly so; subhymenium and hymenopodium well developed, gill trama either regular or showing a mediostratum and lateral strata (between the mediostratum and the hymenopodia on each side); cuticle of pileus consisting of a gelatinous or subgelatinous pellicle or an almost non-gelatinous epicutis (upper layer) and a well-differentiated hypodermium (lower layer), the epicutis (pellicle) of narrow more or less hyaline hyphae, the hypodermium a more compact layer consisting mostly of enlarged hyphal cells but some narrow filaments also present; clamp connections consistently observed on hyphae of all types and at the base of the basidia of the species described below.

Summary or the stirpes

Stirps. Cubensis

Spores medium to large (7.7 µ or more long) and mostly somewhat compressed, in face view obscurely to distinctly angular-ovate to angular-elliptic; veil typically membranous and the remains persisting on the stipe as a membranous annulus; aspect of carpophores not mycenoid; habitat on dung or rotten wood.

The combination of veil and spore characters is diagnostic of the stirps. The presence of a membranous annulus would cause these species to be classified in *Stropharia* in classical taxonomic arrangements, but the lack of chrysocystidia and the presence of a change to blue when injured point to close relationship with the other species of the section. The true *Strophariae* have chrysocystidia or a viscid to glutinous universal veil. Other species such as *P. aztecorum* and *P. candidipes* may at times show a narrow annulus but these have terete or only very slightly compressed spores.

Species included: 1. *P. cubensis*, 2. *P. subaeruginascens*, and 3. *P. aerugineomaculans*.

Stirps. Yungensis

Spores very small (less than 7.7 µ long) and strongly compressed, typically angular-ovate in face view; veil floccose over the lower part of the stipe but not forming an annulus; pileus relatively high or acutely papillate; stipe thin; cap margin incurved at first (general aspect almost mycenoid but with incurved margin); habitat on forest litter and much decayed wood particles in the tropical zone; pigmentation dark, hyphae of the hypodermium heavily incrusted.

The combination of floccose veil and the uniquely small and compressed spores along with the characteristic habit determine the stirps which, so far, contains only a single species.

This stirps has as much in common with the deconicas as the preceding has with the stropharias. It differs, however, in habit and chemical characters from the species usually classified in *Deconica*. Within the section it seems to come closest to the two smaller-spored representatives of the preceding stirps, which are also characterized by relatively small carpophores.

Species included: 4. *P. yungensis*.

Stirps. Mexicana

Spores compressed, medium sized (7-11 µ long); veil thin and poorly developed, not leaving traces on mature carpophores; pileus acute or obtuse in outline except for an apical conic papilla, with straight margin when young, or margin bent in slightly; pellicle poorly developed; stipe thin; habitat characteristically in pastures, fields, meadows, or generally outside the forest in tropical-montane vegetation or plantations.

This stirps forms a natural transition between the preceding and the following one. The spores are still compressed but are not characteristically small; the habit is mycenoid though perhaps slightly less so than in stirps *Silvatica*.

Species included: 5. *P. mexicana*.

Stirps. Silvatica

Spores not compressed, medium (6-9) to large (10-13 µ long); veil thin and not leaving traces in adult carpophores; pileus relatively high and acute, not fully expanding, with straight margin, thus habit mycenoid; pellicle present, thin to thick; habitat in forests on wood and debris, but extratropical (as far as known).

Species included: 6. *P. silvatica*; 7. *P. pelliculosa*.

Stirps. Cyanescens

Spores varying from slightly compressed to terete, typically 9 µ or more long; veil varying from well developed (in *P. aztecorum*) to poorly developed, but never floccose or annulate; habit typically collybioid or nearly so; habitat terricolous or on rotten wood in forests, parks, or among scattered trees.

This combines all the large-spored exannulate species which do not have a mycenoid habit. The spores are not even obscurely angular in face view and are terete or at best only slightly compressed. It is remarkable that the habitat is rather similar in all of them and that none of them can be described as truly tropical.

Species included: 8. *P. aztecorum*; 9. *P. cyanescens*; 10. *P. collybioides*; 11. *P. strictipes*; 12. P. baeocystis.

Stirps. Caerulescens

Spores compressed to terete, small (less than 9 µ long); stipe typically thick (more than 3 mm at apex); veil well developed; habit collybioid to tricholomatoid but not mycenoid; habitat variable.

The species grouped here have well developed veils and rather thick stipe; they are thermophilous in the sense that they all occur in warm climates.

Species included: 13. *P. caerulescens*; 14. *P. aggericola*; 15. *P. candidipes*.

A fourth species which might belong here, *P. zapotecorum* Heim, has not been studied by us. We prefer not to place it formally in one of the stirpes introduced here inasmuch as it might conceivably be closer to some other stirps, or represent a stirps of its own.

Supplement to stirps VI: 16. *P. zapotecorum*.

Stirps. Caerulipes

Spores 7-9(-10)µ long, terete, stipe thin (1-3 mm at apex); veil thin and cortinate; habit collybioid; habitat on rotten wood and debris in the forest and under scattered trees.

But for the small spores and thin stipe this stirps could be united with stirps *Cyanescens*. According to spore size it would be close to stirps *Caerulescens*. But both species are either temperate or montane, and extratropical.

Species included: 17. *P. muliercula*; 18. *P. caerulipes*.

Key to species of section Caerulescentes

1. Annulus typically membranous and persistent ---> 2
   2. Spores 11.5-17.3 µ long ---> 1. *P. cubensis*
   2. Spores smaller ---> 3
      3. Growing on wood; pileus viscid ---> 3. *P. aerugineomaculans*
      3. Growing on dung; pileus merely moist ---> 2. *P. subaeruginascens*

1. Annulus if present merely a zone of fibrils, or very fugacious ---&gt 4
   4. Spores 5-6.5 x 4.3-5 x 3.6-4 µ, strongly compressed; pileus acute ---&gt 4 *P. yungensis*
   4. Spores larger and only somewhat compressed or terete ---&gt 5
      5. Pileus margin straight when young or almost so; habit more or less mycenoid ---&gt 6
         6. Spores compressed (broader in face than in side view); growing in open areas (meadows, fields) ---&gt 5. *P. mexicana*
         6. Spores terete; growing in woods on litter and rotten wood ---&gt 7
            7. Spores 6-9.5 (-11.5) x 4.5-5 µ pellicle thin ---&gt 6. *P. silvatica*
            7. Spores 9.3-11 x 5-5.5 µ (10.5-13 x 5.5-7 µ); pellicle thick and separable ---&gt 7. *P. pelliculosa*
      5. Pileus margin incurved when young; habit typically collybioid ---> 8
         8. Spores typically less than 9 µ long ---> 9
            9. Stipe 10-20 mm thick, 100-200 mm long, cortex very fibrous, hard and elastic ---> 16. *P. zapotecorum*
            9. Stipe not as above ---> 10
               10. Stipe white, basal half scabrous-strigose, upper half strongly floccose from veil ---> 15. *P. candidipes*
               10. Not as above ---> 11
                  11. Veil copious and flocculose in young specimens ---> 12
                     12. Spores in face view 5-6 µ broad; stipe whitish when young ---> 13. *P. caerulescens*
                     12. Spores in face view 4-5 µ broad; stipe colored when young ---> 14. *P. aggericola*
                  11. Veil thin, cortinate, fugacious ---> 13
                     13. Pileus not viscid ---> 17. *P. muliercula*
                     13. Pileus viscid ---> 18. *P. caerulipes*
         8. Spores typically more than 9 µ long ---> 14
            14. Lamellae pallid to white, or brownish only at maturity - sterile to partly sterile collections of *P. collybioides* key out here
            14. Not as above.
               15. Stipe whitish; pileus milk white or disc merely ochraceous ---> 8. *P. aztecorum*
               15. Stipe or pileus or both more deeply colored ---> 16
                  16. Pileus chestnut color; spores slightly compressed ---> 9. *P. cyanescens*
                  16. Not as above ---> 17
                     17. Cheilocystidia 20-30 (-36) x 4-6 x 1.2-1.5 µ ---> 12. *P. baeocystis*
                     17. Cheilocystidia larger ---> 18
                        18. Odor distinctive - variable, farinaceous to raphanaceous to spermatic ---> 10. *P. collybioides*
                        18. Odor none; taste mild ---> 19
                           19. Stipe 100-130 mm long, straight ---> 11.

P. strictipes
19. Stipe up to 70 mm long. *H. cyanescens* sensu Malençon (see under *P. collybioides*)

Stirps Cubensis

Psilocybe cubensis (Earle) Sing

1. ***Psilocybe cubensis*** (Earle) Sing., Sydowia 2: 37. 1948. (Fig. 1-3, 40-41.)
Stropharia cubensis Earle, Est. Agron. Cuba 1: 240. 1906.
Naematoloma caerulescens Pat., Pull. Soc. Mycol. Fr. 23: 78. 1907.
Hypholoma caerulescens (Pat.) Sacc. & Trott. in Sacc., Syll. Fung. 21:212. 1912.
Stropharia caerulescens (Pat.) Sing., Ann. Mycol. 34: 340. 1936.
Stropharia cyanescens Murr., Mycologia 33: 279. 1941.

Pileus 16-80 mm. broad, conic campanulate with an acute papilla at first, gradually becoming convex to plane and at times with a depression around the umbo, umbo becoming more obtuse, more rarely without any umbo or papilla, viscid, glabrous or with fugacious veil remnants near margin, white with more or less fulvous center, eventually entirely fulvous brown, sometimes white to pale yellow ("cartridge buff") at margin, more "cream buff," "chamois," or "honey yellow" toward the "Isabella color" to "clay color" disc, usually staining bluish in age or when injured.

Lamellae gray, becoming deep violet gray and somewhat mottled, finally almost black, adnate to adnexed, seceding, close, narrow, becoming ventricose in mid-portion, broad in age, edges white.

Stipe 40-150 x 4-14 mm, tubular, usually somewhat thickened downward, more rarely subequal, or tapering to the base, white, staining blue ("deep Medici blue") when injured, eventually discoloring to yellow brown or reddish cinereous, often strongly sulcate at the apex, smooth otherwise, glabrous to slightly fibrillose, dry; annulus membranous but thin, smooth on both sides, white, staining blue, fragile, usually persistent.

Context white, staining blue on injury; odor none; taste farinaceous.

Spores 11.5-17.3 x 8-11.5 x 7-9 µ, dark yellow brown (in KOH) to dark olive brown (in NH_4OH), smooth, nearly elliptic in side view, ovate to broadly elliptic in face view and many obscurely angular, wall thick and complex, apex truncate from a distinct apical pore; basidia (2-, 3-, or) 4-spored, 28-35 x 10-13 µ; pleurocystidia scattered, 18-23 x 10-13 µ, ventricose and narrowed slightly near apex to an obtuse to rounded tip, thin-walled, contents (in KOH) homogeneous (not protoplasmatic); cheilocystidia numerous, 18-35 x 6-12 µ, fusoid-ventricose with obtuse to subcapitate apex, neck 4-18 µ long, 3-6.5 µ thick, enlarged tip (head) 4-5 µ, wall thin and readily collapsing; gill trama regular, mediostratum of hyaline parallel to somewhat interwoven hyphae, in well pigmented caps this layer flanked on both sides by parallel hyphae with dingy ochraceous walls (in KOH); pellicle of pileus a thin layer of narrow (c. 3.5 µ) gelatinous hyphae which are radially arranged and yellowish to hyaline in KOH; hypodermium of interwoven to more or less radial hyphae up to 26 µ in diameter, with ochraceous brown walls in KOH; clamp connections present.

Chemical characters: metol strongly positive on context of stipe ("dark naphthaline violet" or darker), other reagents negative or accelerating the bluing.

Gregarious on cow dung, more rarely on horse dung or on rich pasture soil, or on sugar cane mulch or straw or sawdust mixed with dung, usually outside the forests, fruiting from February until November or December, south of the Equator from November until April.

Material studied: U.S.A., Florida: TYPE of *Stropharia cyanescens* Murr. and additional collections by *G. F. Weber*, *J. R. Watson*, and *W. A. Murrill*, as *S. cyanescens*, F-19138, F-19630, F-19244, F-17932, F-17735, F-19464 (all FLAS), and *R. Singer F 1802, F 1802a* (FH, F); Magnesia Springs, *W. A. Murrill* (NY). Puerto Rico: Mayaguez and Ailonato, *Bruce Fink 899* and *1955* (NY). Cuba: Santiago de las Vegas, *Earle 109* both on sheets and in box, marked "tipico," TYPE of *Stropharia cubensis* (NY); also *Earle 169, 315, 350*; Candelaria, *Earle 206*

(NY); Soledad, Cienfuegos, *W. L. White 808,526* (FH). Mexico: Oaxaca, Huautla de Jiménez, *7-27-38*, *R. E. Schultes*, Plantae Utiles Mexicanae 349 (FH); *R. Gordon Wasson 1* (NY); *R. Singer M 1512* (MICH). Brit. Honduras: *M. E. Peck 478* (NY). Trinidad (collector not given) (NY). Bolivia: Beni, Guayaramerín, *R. Singer B* (LIL). Argentina: Tucum'n, *R. Singer T* (LIL). Indochina: TYPE of *N. caerulescens* Pat. (FH).

The collections enumerated above should be divided into three color varieties:

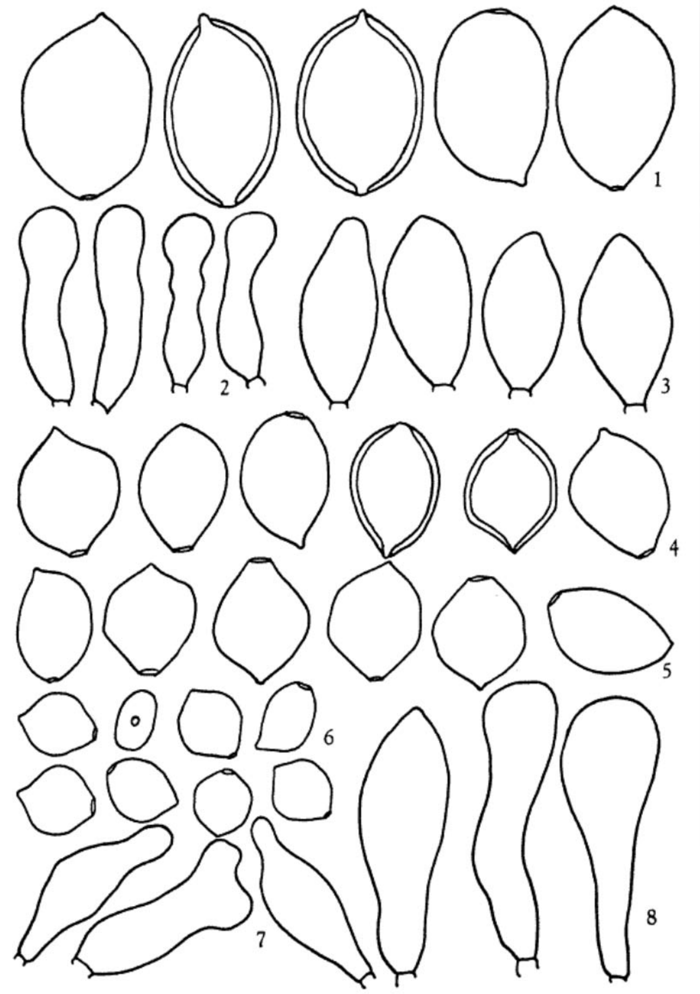
P. CUBENSIS var. CUBENSIS (the type). Here, the pigmentation of the pileus is fulvous. It develops early, and pallid pilei are hardly ever seen. The strain proved to be hallucinogenic belongs here.

P. CUBENSIS var. **cyanescens** (Murr.) comb. nov. The type of this variety is the type of *Stropharia cyanescens* Murr. It differs from the type variety in the virtual lack of pigment or its small quantity; consequently the pileus is pallid to pale isobelline. Known to occur in Florida (10).

P. CUBENSIS var. **caerulescens** (Pat.) comb. nov. The type of the variety is *Naematoloma caerulescens* Pat., type. It differs from the type variety in showing a clear yellow color at least in certain portions of the pileus. Known to occur in Indochina (11).

Illustrations: V. P. & R. G. Wasson, Mushrooms Russia and History 2: *pl. 40, fig. 2*. 1957; Life, May 13, 1957, p. [107] *fig. at lower right*. (Both the *var. cubensis*.)

The senior author at one time (14) thought that *Stropharia caerulescens* Imai (*S. venenata* Imai) was identical with *S. cubensis*, but we are treating it now as synonymous with a closely related but distinct species. For more detailed commentary on *S. venenata* see under *P. subaeruginascens*.



Figs. 1-8. 1-3: spores, cheilocystidia and pleurocystidia of *Psilocybe cubensis*. 4: spores of *P. subaeruginascens*. 5: spores of *P. aerugineomaculans*. 6-8: spores, cheilocystidia and pleurocystidia of *P. yungensis*.

Psilocybe subaeruginascens Höhnel

2. ***Psilocybe subaeruginascens*** Höhnel, Sitzungsber. K. Akad. Wiss. Wien 123(1): 78. 1914. (Fig. 4.)
Stropharia caerulescens Imai, Trans. Sapp. Nat. Hist. Soc. 12: 148. 1932.
Stropharia venenata Imai, Journ. Fac. Agr. Hokk. Imp. Univ. 43(2): 270. 1938.

Pileus 15-25 mm broad, plano-convex, almost membranaceous, glabrous and smooth, whitish with smoke brown center, becoming slightly greenish-blue-spotted when touched.

Lamellae grayish brownish, rather distant, with paler edge, 2-3 mm broad, broadly adnate and somewhat decurrent.

Stipe 30-40 x 1.5-3 mm, cylindric, slightly thickened at base, somewhat flocculose-farinaceous above, otherwise glabrous, somewhat shining, hollow but stuffed with a loose woolly pith, white, weakly greenish blue when touched, with an annulus above the center of the stipe, annulus small, often oblique, scaly-membranous; mycelium abundant, filamentous, white, staining greenish blue or almost steel blue.

Context white, tough in the stipe, bluing; odor and taste not recorded.

Spore deposit beautifully violet-brownish.

Spores 7.7-10 (-11.5) x 7-7.8 x 6-7 µ, ovoid to subrhomboid in face view, in side view somewhat inequilateral, smooth, dingy yellow brown in KOH, apex truncate from a broad flattened germ pore; basidia 2- and 4-spored, very rarely 1-spored or 3-spored, 18-28 x 6.3-0.2 µ, typically with a median constriction; pleurocystidia 25-33 x 9-12 µ, broadly fusoid-ventricose with obtuse apex, hyaline, thin-walled, contents homogeneous; near the edge sometimes some pleurocystidia similar to cheilocystidia; cheilocystidia 20-33 x 6-9 µ, fusoid-ventricose with obtuse apex or neck narrow and cylindric, or in some the apex subcapitate, hyaline, causing the edge to appear heteromorphous; epicutis of pileus not gelatinous, apparently of closely interwoven appressed hyphae; clamp connections present.

Subcespitose on horse dung, Buitenzorg, Java, Indonesia, *v. Höhnel*, TYPE (FH).

This is a *Psilocybe* of the *P. coprophila* type but staining blue. The spores are more angular in face view than those of *P. coprophila* and also of smaller size.

Stropharia caerulescens Imai (5) is placed in synonymy here although the type is unavailable at present; we base our judgment on the following original description:

Pileus 15-60 mm broad, glabrous, hygrophanous, or scarcely slightly viscid, convex to plane to subumbonate, yellowish to isabelline, more rarely whitish, margin always pallid. Lamellae pallid, then violet fuscous, adnate. Stipe 35-90 x 5-9 mm, equal, dry, almost hollow, fibrillose below the annulus, whitish, annulus almost apical, very thin membranous, more rarely fibrillose, often evanescent. Context whitish or pallid, bluing. Spores fuscous or violet fuscous, ellipsoid, 7-10.5 x 4.25-7 µ; cystidia none. Gregarious or cespitose on earth and dung, fruiting in June, July and October. Japan, Hokkaido, Ishikari province, near Asahigawa and Sapporo. [Specimens are apparently preserved at Sapporo.]

It is interesting to read in Imai's account (5) about the physiological activity of this species. It caused ten deaths in 1929 alone, and is apparently more toxic than the related Mexican species. The symptoms are described as feeling feverish, with a subjective impression as if strong liquor had been imbibed; the limbs became somewhat paralyzed. In the hospital after an emetic had been administered and the stomach washed and eventually a laxative had been given, the patient was now in bed with intermittent constriction or trembling of muscles and finally there were hallucinations, then coma. This patient, a woman, recovered. Her son who did not eat the flesh of the mushroom but drank only the liquid of the soup in which it was cooked felt only paralysis of the limbs and a chill, followed by hallucination. All recovered eventually.

In another case, after similar symptoms were observed, coma, loss of consciousness, and talking in delirium were observed. The pupils had opened to a medium size and did not react to light. (This observation coincides with observations made in Mexico with psilocybes of this section.) For more details see Imai's paper (5).

In a later paper (6), Imai renamed his species *S. venenata* Imai. The description was now slightly changed to accommodate also specimens with deeper color of the pileus, more viscid surface, and habitat on rotten wood. The conclusion is very suggestive that the forms later added to the species concept and expressed in the changes of the description at the time of the publication of *S. venenata* can be accounted for if it is assumed that the type form (= *P. subaeruginascens*) was later confused with *P. aerugineomaculans*. Whether this opinion is correct can be proved only if and when specimens from Japan become available.

The original description of *S. caerulescens* Imai is accompanied (p. 149) by a photograph which, by implication, and with certain reservations, may be cited as an illustration of *P. subaeruginascens* Höhnel.

Psilocybe aerugineomaculans (Höhne)

3. ***Psilocybe aerugineomaculans*** (Höhnel) comb. nov. (Fig. 5.)
   Stropharia aerugineomaculans Höhnel, Sitzungsber. K. Akad. Wiss. Wien 123(1): 78. 1914.

Pileus 25-40 mm broad, campanulate, becoming expanded and umbonate, surface slightly viscid to the touch, disc dark blue, remainder reddish gray-cinereous (as in *Psathyrella gracilis* sensu Höhnel), margin striatulate.

Lamellae rather distant, 4-5 mm broad - *i.e.*, moderately broad - attenuate-adnate, yellowish olive, marbled as in *Panaeolus*, edges even.

Stipe 40-50 x 2 mm, not thickened at base, cylindric, hollow, white, slightly flocculose, glabrescent, shining, annulus membranous, small, entire, white; rind 0.15 mm thick when dried.

Context in the middle of the pileus thin (2 mm), membranous toward margin, somewhat cartilaginous in outer layer of stipe, soft inside, staining blue where bruised; odor and taste not recorded.

Spore deposit very deep brown, almost black.

Spores 8.5-10.5 x 7-8 x 5.5-6.5 µ, compressed, subelliptic in side view, rhombic to heart-shaped (angular ovate) in face view, with a truncate apex and a distinct germ pore, thick-walled, near bister when revived in KOH; basidia 4-spored, about 22 x 8 µ; pleurocystidia not seen in type; cheilocystidia 18-22 x 6-8 x 3.5-4 µ, fusoid-ventricose with obtuse apex, typically capped with a hyaline mucilaginous substance, the whole gill edge gelatinizing in KOH; pellicle of pileus distinct but formed by a thin layer of gelatinized epicuticular hyphae; clamp connections present.

On rotten wood. Buitenzorg, Java, Indonesia, *v. Höhnel*, type (FH).

Although the species is lignicolous, the spores remind one of the coprophilous series. The presence of a distinct gelatinous pellicle separates this species from *P. subaeruginascens*. This was clearly demonstrated from a study of the types. The type of *P. subaeruginascens* is well dried, well preserved, and consists of fruiting bodies that were in prime condition when placed on the drier. Hence, the lack of a gelatinous epicutis is significant. The type of *P. aerugineomaculans* consists of two carpophores which were apparently over-age when dried and as preserved are inferior to quality to those of *P. subaeruginascens*. Under such circumstances one would expect the gelatinous pellicle, if one were present originally, to be pretty well obliterated. The fact that it is still present indicates to us that when fresh material is again collected the pellicle may be found to be rather thick and well developed.

From our comments on *P. subaeruginascens*, one might expect *P. aerugineomaculans*, no less than *P. subaeruginascens*, to occur in Japan.

The macroscopical descriptions of both Javanese species are adapted from Höhnel's notes.

Stirps Yungensis

Psilocybe yungensis Singer and Smith

4. ***Psilocybe yungensis*** Singer and Smith, Mycologia 50: 142. 1958.
   Var. yungensis (Figs. 6-8, 45).

Pileus about 16 mm broad and equally high, margin at first incurved, conic with an obconic or button-like appendage at the tip, not expanding, deep rusty brown (*leaf mold*), in the marginal region between striae buffish gray (*cracker*), finely marked with long translucent striations when moist, somewhat viscid, staining deep blue (*39 H 5*) where injured.

Lamellae gray buff (*aloma*), with white edges, staining blue where wounded (*39 H 5*), very narrow, ascending and never becoming horizontal, crowded, adnate.

Stipe 55 mm long, 2 mm at apex, 3 mm at base, subequal, deep chestnut brown (Hindu), reaching auburn at apex, bluing less than cap and gills but such a change still evident, densely fibrillose floccose from light brownish fibrils on darker ground, becoming more fibrillose-pruinose toward apex, veil inconspicuous except for the floccons, no annulus formed.

Context concolorous with surfaces or somewhat paler both in pileus and stipe, moderately fragile in stipe; odor slightly raphanaceous.

Spore deposit dark lilac.

Spores 5-5.5 x 4.3-5 x 3.6-3.9 µ, compressed, dark olive sepia in KOH and NH_4OH, smooth, rhombic in face view and a hilar appendage visible, without suprahilar applanation or depression in side view, apical pore broad, wall thick and complex; basidia 13-18.5 x 4.7-6.2 µ, short-ellipsoid-clavate then elongating and finally ventricose in the middle 2-, 3-, or mostly 4-spored, hyaline; pleurocystidia present as an occasional cystidiole about the size of a basidium, but often with a low mucro, contents hyaline in KOH and not protoplasmatic; cheilocystidia 13-34 x 5-7.3 µ forming a sterile band along the edge, exceptionally variable: some clavate, some ventricose and with capitate to subcapitate apex, some ventricose above and constricted in the middle, others ventricose-fusoid and broadest in mid-portion, some ampullaceous, some capitate-cylindric, some subulate-sublanceolate, all hyaline, narrowest portions 2.7 µ or more; subhymenium of small irregular elements, not regularly arranged; with a brown to stramineous membranal pigment which often breaks up to incrust the walls of the cells; gill trama regular, consisting of elongate cylindric elements, pigmented like the subhymenium, with 0.8-1 µ thick walls; epicutis gradually more differentiated from the hypodermium toward the uppermost surface of the pileus, there often more or less gelatinized, with smooth hyaline filamentous elements subparallel, forming a cutis, ascending hyphal excrescences often present on these hyphae and some of these stramineous and incrusted; hypodermium of a compact layer of hyphae irregular in size and shape but generally repent and radially elongated, all strongly incrusted with ochraceous brown pigment; clamp connections present.

Chemical characters: KOH leaving a dark spot where dropped on any part of the carpophore; $FeS0_4$, no reaction.

In small to large groups on very rotten wood or humus containing decomposing woody material, in tropical-montane forest, fruiting in January (summer rainy season). Known only from the type locality, Cataratas de San Juan, road from La Paz to Coroico, Bolivia, 2000 m alt., 1-28-1956, *Singer B 648*, TYPE (MICH).

Var. diconica Singer and Smith, Mycologia 50: 142. 1958. (Fig. 44)

Pileus as in the preceding variety but lower, with an acute papilla rather than a knob, not quite so long-striate and somewhat darker in color (*Mohawk*, and between striae *kis kilim*).

Lamellae sordid lilac or reddish brown (between *kermanshah* and *Rembrandt*), otherwise as in var. *yungensis*.

Stipe shorter than in the preceding variety.

Context odorless.

Spores 4.4-6.2(-7.2) x 3.8-5 x 3.3-3.8 µ, otherwise as in var. *yungensis*; basidia mostly 4-spored; pleurocystidia and cheilocystidia as in preceding variety; gill trama consisting of broad, often short, stramineous hyphae with thick walls; epicutis and hypodermium of pileus as in preceding variety; clamp connections present.

Chemical characters as in var. *yungensis*.

Gregarious on very rotten wood and humus in tropical-montane forest. Bolivia, Departamento La Paz, Provincia Nor-Yungas. Cataratas San Juán, 2000 m alt., *R. Singer B 651*, TYPE, 1-28-1956 (MICH).

The two forms designated temporarily as varieties come from the same place and were gathered the same day as separate populations. Each population had its own characteristic habit and color range as described above, but under the circumstances we did not think them sufficiently distinct to separate them specifically. They were considered "probably the same" when first collected in the field.

P. yungensis is a very strongly pigmented species with typically high, little or not expanding pileus but with originally incurved margin, and with a non-annular veil remaining in floccons on the surface of the thin stipe. The spores are different from those of all other species of this section.

Stirps Mexicana

Psilocybe mexicana Heim

5. ***Psilocybe mexicana*** Heim, Rev. de Mycol. 22: 77. 1957. (Fig. 25-26, 43)

Pileus 5-33 mm broad, 4-15 mm high, conic-campanulate and usually with a central papilla, frequently becoming hemispheric to convex and sometimes papillate in addition, broadly conic in others, and becoming umbonate and in these the umbo sometimes crowned by a papilla, always relatively high and narrow and not fully expanded, eventually, however, often convex with an uplifted margin, glabrous, viscid but soon dry, margin at times sulcate-striate to a small apical smooth disc, disc deep ochraceous to ochraceous brown, then fulvous, marginal zone much paler, hygrophanous, fading to ochraceous over the disc, gray brown in marginal zone and pale ocher-gilvous between, all traces of silky white veil soon vanishing from the margin.

Lamellae pale gray, eventually deep sepia, close to subdistant, ascending to almost horizontal, adnate to adnexed, only moderately broad, edges whitish.

Stipe 20-80 x 1-3 mm, hollow, equal and elongate, sometimes rather distinctly attenuated at the base, ochraceous, at maturity the apex paler, central portion often fulvous, glabrous when mature; veil thin and leaving fine appressed silky fibrils on the upper third, soon evanescent.

Context in pileus paler than surface, turning blue when bruised or on drying; odor always rather strongly farinaceous; taste slightly disagreeable.

Spore deposit deep sepia to dark purple brown.

Spores (7.7-)8.8-10.5(-12) x (5.5-)6.7-7.7 x (5-)5.5-6.7 µ, compressed, in face view elliptic to rhombic and then broadest in mid-portion, subelliptic in side view, dingy yellowish brown in KOH, smooth, with thick walls, furnished with a distinct broad germ pore; basidia 20-32 x 6.3-7.7 µ, 4-spored, variable in size, typically with a median or more superior constriction; pleurocystidia none, or a few similar to cheilocystidia near the edge; cheilocystidia forming a sterile band along edge, 15.5-30.5 x (3-)4-9 µ, usually short pedicellate, hyaline, fusoid-ampullaceous, the neck short (rarely long), apex obtuse to acute (rarely capitate or bifurcate); subhymenium a thin layer of very irregular small elements; hymenopodium of relatively narrow filamentous axially arranged parallel hyphae, layer thin; gill trama regular, hyaline to stramineous, with voluminous (up to 19 µ in diameter) elements, hyphal walls up to 1.5 µ in diameter; epicutis a broad hyaline layer of filamentous mostly hyaline hyphae, not strongly gelatinized but well differentiated from hypodermium, hyphae 1.7-3.5 μ in diameter; hypodermium a colored (yellowish brown) layer of hyphae 2-14 μ in diameter, with pigment in the walls (not incrusted); body of context hyaline to yellowish, many hyphae up to 20 μ in diameter and walls up to 1.5 μ thick; dermatocystidia none; clamp connections present.

On the earth or on plant fragments such as mulch from sugar cane presses, usually in open fields and springy meadows, never on dung; always solitary but often in large numbers in a limited territory; fruiting from May until October, common in the transition zone between the tropical-montane and the temperate-montane zone - *i.e.*, between 1500 and 1800 m alt. - favoring limestone regions. Reported from Southern Mexico and Guatemala.

Illustrations: Wasson, Mushrooms Russia and History 2: *pl. 40, fig. 1*; Life, May 13, 1957, p. [107], *fig. at lower left*.

Material studied: Mexico: Oaxaca, Huautla de Jimenez, *R. G. Wasson 3*, 13-8-1953 (NY); *R. Singer M 1502*, July 10, 1957 and *M 1521*, July 11, 1957 (both MICH).

This is the only mycenoid representative of the genus occurring in Oaxaca and consequently the only mycenoid hallucinogenic mushroom used by the Mazatecs. For this reason it is sometimes confused with *Panaeolus sphinctrinus* which has a similar habit but is more obtuse, with blacker lamellae, and grows mostly directly on dung.

Stirps Silvatica

Psilocybe silvatica (Peck)

6. ***Psilocybe silvatica*** (Peck) comb. nov. (Figs. 27, 29).
   Psathyra silvatica Peck, Ann. Rep. N. Y. State Mus. 42: 20. 1889.
   Hypholoma silvaticum (Peck) A. H. Smith, Contrib. Univ. Mich. Herb. 5: 21. 1941.

Pileus 8-25 mm broad and at least half as high, obtusely conic to campanulate, margin straight at first, disc often with a papilla, glabrous, viscid, shining when dried, tawny to rather dark brown, hygrophanous, fading to pale ochraceous buff to grayish melleous or grayish brown.

Lamellae dull ferruginous brown when mature, narrow to broad, adnate, ascending to almost horizontal, close to subdistant, with a pallid edge.

Stipe 20-80 x 1-3 mm, equal or slightly thickened at the base, tubular, flexuous, pallid to brownish, apparently whitish from a superficial appressed fibrillose covering, this layer thinning out downward and more brown showing through from cortex of the stipe; veil apparently very weakly developed and all traces gone in mature specimens.

Context in pileus membranous and fragile, in stipe brownish and cartilaginous; taste farinaceous; odor also farinaceous (from crushed flesh).

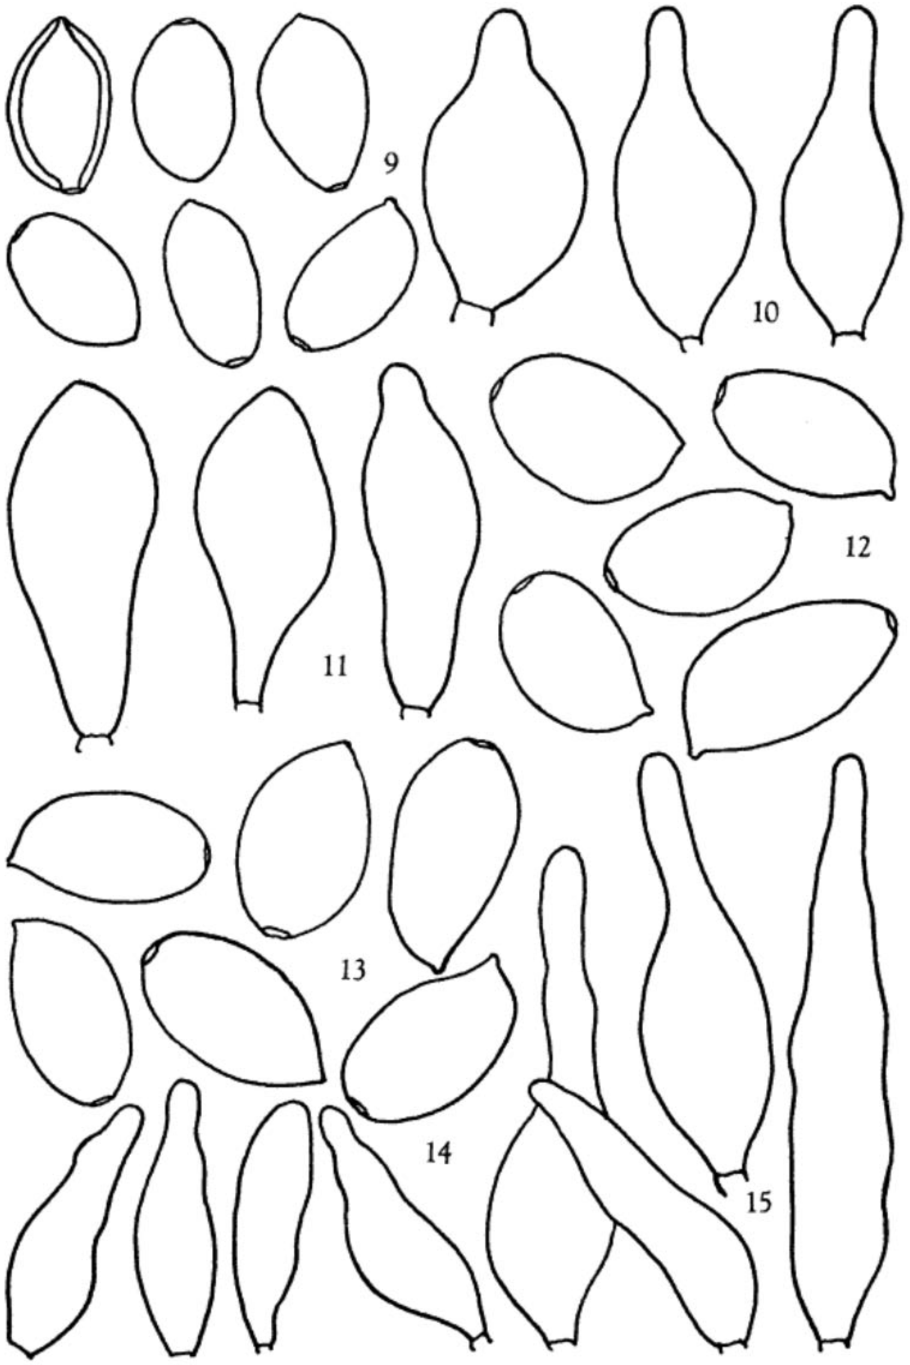
Spores in deposit "benzo brown" (violaceous brown).

Spores 6-9.5(-11.5 from 2-spored basidia) x 4.5-5.5 μ, dingy yellowish brown in KOH, smooth; with a complex thick wall, terete in cross section, with a distinct apical germ pore; basidia 19-27 x 5.7-8 μ, 4-spored, rarely 2-spored; pleurocystidia none; cheilocystidia 24-45 x 4-10 μ, ventricose below and often ampullaceous with an elongated neck 1.3-2.2 μ thick, tapering to an obtuse to (rarely) subacute apex, often pedicellate, forming a sterile band on gill edge; subhymenium thin, melleous in KOH; gill trama of relatively broad hyphae with walls up to 0.8 μ thick, pale melleous in KOH and lacking pigment incrustations; epicutis of pileus a thin pellicle of gelatinized hyaline to yellowish filaments 1-2.8 μ in diameter, but pellicle not very strongly gelatinous; hypodermium of compactly arranged hyphae 3 μ or more broad and more highly pigmented than in trama proper, pigment incrusting the walls; clamp connections present.

In small groups, gregarious but not cespitose, in the woods on debris around stumps or on leafmold (mostly *Fagus grandifolia*), generally not directly on stumps or logs, fruiting in September and October. Known from New York, Ontario, and Michigan.

Material studied: U.S.A.: New York, Star Lake, *Peck*, PARATYPE of *Hypholoma fragile* (NYS); North Elba, *Peck*, TYPE (NYS). Mich., Milford, *Smith 20970*, 10-4-1949 (MICH). CANADA: Ont., Bear Island, Lake Timagami, *Smith 4777*, 9-9-1936 (MICH).

Hypholoma fragile was originally reported by Peck from two localities, Star Lake and Painted Post, both in New York. As A. H. Smith (18) previously pointed out, the Painted Post collection should be regarded as the type. This latter is a *Psathyrella* and the same as *P. hymenocephala* (Peck) Smith. The Star Lake collection is *P. silvatica* (Peck) Sing. & Sm.



Figs. 9-15. 9: spores of *Psilocybe aztecorum*. 10: cheilocystidia of *P. collybioides*. 11: pleurocystidia of *P. collybioides*. 12 and 15: spores and cheilocystidia of *P. strictipes*. 13: spores of *P. baeocystis*. 14: cheilocystidia of *P. candidipes*.

When A. H. Smith (17) described *P. pelliculosa* the confusion involving *H. silvaticum* had not been discovered. After working out the details of this problem he considered the apparently slight differences existing between *P. pelliculosa* and *P. silvatica* as of no taxonomic significance and reduced *P. pelliculosa* to synonymy with *P. silvatica*. It now appears from the study of all known species in this section that the slight differences disregarded earlier may have taxonomic significance and so *P. pelliculosa* is re-established here.

Psilocybe pelliculosa (Smith)

7. ***Psilocybe pelliculosa*** (Smith) comb. nov. (Figs. 28, 30, 42).
   Psathyra pelliculosa A. H. Smith, Mycologia 29: 58. 1937.

Pileus 8-15 (-30) mm broad, at least half as high as broad, obtusely conic with a straight margin when young, remaining so or becoming more broadly conic-campanulate, never fully expanding, surface glabrous, smooth, viscid from a separable gelatinous pellicle, hygrophanous, "Saccardo's umber" to "Isabella color" (dark dingy yellow-brown or more olive showing), usually fading to "pinkish buff" (dull pale alutaceous), often with greenish gray tints in age, margin translucent-striate when moist.

Lamellae dull "cinnamon brown" until darkened by the spores, adnate but eventually separating from the apex of the stipe, rather narrow to moderately broad, markedly ascending at first, less so in age, close, edges pallid.

Stipe 60-80 mm long, 1.5-2 mm thick at apex, equal above an enlarged base (base enlarged from adhering debris), pallid to grayish, appressed silky fibrillose and brownish below and reaching bister in age, pruinose above; veil absent to rudimentary.

Context thin and pliant in pileus, rather tough in stipe, turning slightly bluish or greenish where injured in pileus and stipe; odor none or slightly musty.

Spores 9.3-11 x 5-5.5 µ to 10.5-13(-14) x 5.5-7 µ (according to populations, all 4-spored), dark yellow brown in KOH, showing a distinct apical germ pore (often convex), smooth, terete, ellipsoid to subovoid; basidia 4-spored, 22-30 x 7-8 µ, hyaline; pleurocystidia none or only near gill edge and similar to cheilocystidia; cheilocystidia 22-36 x 5.5-7.5 µ, hyaline, forming a sterile band on gill edge, often pedicellate, fusiform-lanceolate with an elongated neck tapering to an acute to subacute apex, neck rarely cylindric with an obtuse apex, hyaline in KOH; subhymenium narrow and irregular, brownish in KOH; gill trama regular, pale brownish in KOH; epicutis of pileus a thick pellicle of more or less horizontal very loosely arranged strongly gelatinized wavy hyphae 0.8-5.5 µ in diameter, hyaline, walls never incrusted; hypodermium of compactly subparallel hyphae tawny from having colored walls but walls not incrusted; all hyphae with clamp connections.

Scattered to gregarious or cespitose on debris and humus in and near conifer forests from September to December. California, Oregon, Washington, Idaho.

Illustration: A. H. Smith in Contrib. Univ. Mich. Herb. 5: *pl. 10, fig. 1* (*Hypholoma silvaticum*). 1941.

Material studied: Idaho: Granit Creek, Nordman, *A. H. Smith 54268*, 10-8-56 (MICH). Washington: Lake Cushman, Olympic Mts., *C. H. Kauffman*, 10-11-15 (*Psathyra fagicola*) (MICH); Lake Quiniault, *C. H. Kauffman*, 10-13/27-25 (all three MICH); Lake Crescent, *A. H. Smith 3074*, 10-10-35 (MICH); numerous other collections from nearby places in Washington: *A. H. Smith 3196, 17875, 39887, 40212, 40465/6, 40526, 40966, 41181, 49088, 49381*; Zenith, *J. B. Flett*, 11-3-41 (all MICH). Oregon: Near Lake Tahkenitch, *A. H. Smith 3431*, 11-11-35, TYPE (MICH); other Oregon collections, *A. H. Smith 3461, 7893, 9298, 25057, 49488* (all MICH). California: Crescent City, *A. H. Smith 8260*, 10-30-37 (MICH).

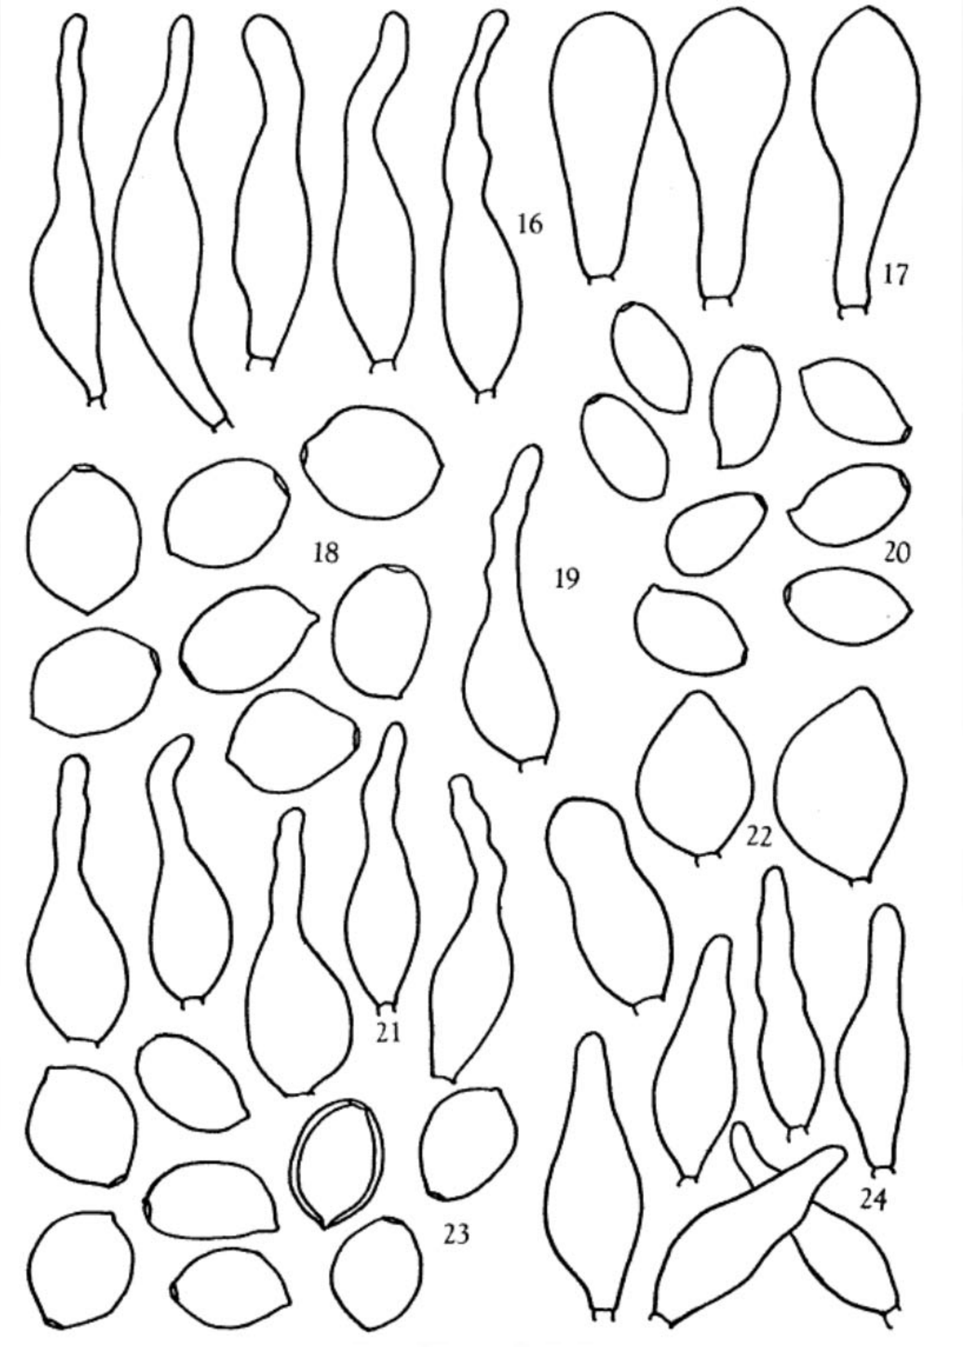
Stirps Cyanescens

Psilocybe aztecorum Heim

8. ***Psilocybe aztecorum*** Heim, Rev. de Mycol. 22: 78. 1957 (Figs. 9, 31).
   Psilocybe mexicana var. *longispora* Heim, C. R. Acad. Sc. 244: 1393. 1956, nom. subnud.

Pileus 15-25 mm broad, obtuse to subumbonate, expanding to broadly conic or campanulate, glabrous except for traces of the veil along margin at first, slightly viscid, hygrophanous, milk white with yellowish disc, striate over about a third of the radius when moist, pale buff faded, disc tending to become rimulose-cracked in some specimens.

Lamellae deep purple brown when mature, adnate, broad, fairly close, with pallid to whitish edges.



Figs. 16-24. 16: cheilocystidia of *Psilocybe baeocystis*. 17 and 20: pleurocystidia and spores of *P. candidipes*. 18, 19, 21 : spores, pleurocystidia and cheilocystidia of type of *P. caerulescens*. 22-24: pleurocystidia, spores and cheilocystidia of *P. mazatecorum* (Mexican specimens so determined by Heim) = *P. caerulescens*.

Stipe 30-60 mm long, 2-4 mm thick at apex, equal or nearly so, fibrous, base at times enlarged, often flexuous, whitish, staining blue, becoming grayish on discolored portions, especially over lower part in age; veil well developed, sometimes forming a fugacious annulus.

Context white, changing to blue readily, especially in the stipe; odor farinaceous; taste astringent.

Spores 10.5-14(-16.2) x 5.3-7.7 (-8.8) µ, elongate-ellipsoid, terete, revived in KOH dark dull ochraceous brown with olive tone and a red brown line showing along the endosporium, thick-walled, germ pore broad and distinct, wall smooth; basidia hyaline to melleous-hyaline, mid-portion usually constricted, 24-31 x (5-)7.7-10(-10.5) µ, (1-, 2-, 3-) 4-spored, sterigmata 6-6.5(-7.8) µ long; pleurocystidia similar to cheilocystidia, rare to scattered, rarely a few cystidioles found, their shape reminding one of one-spored basidia; cheilocystidia abundant, causing gill edge to be heteromorphous, 24-45 x 5-8 µ, fusoid-ampullaeeous with filamentous neck, neck rarely tapered sharply to a subacute apex, 6-11 µ long and about 2.5 µ in diameter; pilocystidia none; caulocystidia abundant near apex of stipe, variable in shape, 17-43 x 4-9 µ, ventricose at base and with or without a short neck; epicutis a thin pellicle consisting of narrow (1-2.2 µ) gelatinized hyphae hyaline in KOH; hypodermium poorly differentiated but hyphae up to 14 µ broad, having colored (non-incrustcd) walls and not gelatinized; clamp connections present.

In small groups on the earth in open pine woods (*Pinus hartwegii*), associated with grasses and *Alchemilla procumbens*. It fruits in September and is known only from around Paso de Cortés, Mexico and Puebla, between 3300 and 3700 m elevation, Mexico. *G. Guzmán VA 1099*, September 1957, TOPOTYPE (MICH).

Illustrations: Singer, Chicago Nat. Hist. Mus. Bull. Dec. 1957 (photo); *Life*, May 13, 1957, p. [106], *upper fig*.

In this species are combined the characters of small carpophore size, large spore size, and fairly copious veil development. It is only slightly - never abundantly - pigmented, but the fact that it turns blue when injured has been very clearly established by G. Guzmán on the material on which our description is based, and the local inhabitants likewise consider the bluing one of the mushroom's characteristic features.

Psilocybe cyanescens Wakefield

9. ***Psilocybe cyanescens*** Wakefield, Brit. Mycol. Soc. Trans. 29: 141. 1946.

Pileus 20-40(-75) mm broad, convex, becoming expanded, viscid, hygrophanous, when moist chestnut color, fading yellowish or ochraceous, margin striate when moist, staining blue when touched.

Lamellae cinnamon colored becoming badio-fuscous as spores mature, adnate to adnate-decurrent, subdistant, up to 5 mm broad, edges paler.

Stipe 60-80 x 2.5-5 mm (rarely 100 x 7 mm), fairly rigid, base somewhat enlarged and often curved near the base, whitish, silky fibrillose, changing to blue when bruised or in drying; veil cortinate, snow white and thin, best seen on young fruiting bodies.

Spore print fuscous.

Spores 9-12 x 5.5-8.3 x 5-7.7(-8) µ, mostly slightly broader in face than in side view, smooth, nearly elliptic in side view, more ovate in face view, with a distinct broad apical germ pore, wall thick and complex, dingy yellow-brown in KOH and with a reddish chestnut line along the endosporium; basidia 4-spored, 16-26 x 7.2-9.3 µ, cheilocystidia 12-26 x 5-8 µ, fusoid-ventricose, with the neck 2-4 µ thick and projecting about one-third of the total length of the cheilocystidium, apex obtuse; pleurocystidia few, in form of cystidioles, 21-28 x 5.5-8.8 µ, resembling basidioles but mucronate and lacking both protoplasmatic granulation and refractive internal body when revived in KOH (hence neither basidioles nor chrysocystidia); gill trama regular, hyaline to melleous, the hyphae lacking pigment incrustations and having thin to moderately thickened walls; epicutis a pellicle of long loosely arranged filaments imbedded in a gelatinous mass; beneath this a hypodermium of melleous but not conspicuously incrusted hyphae; pilocystidia none; clamp connections present.

On the earth among leaves and dead twigs in woods, perhaps occasionally on rotten wood, known only from

Kew Gardens, Surrey, England, TYPE (K).

The description of the field characters is translated from the original description. The data on microscopical characters were obtained by us from a study of the type.

It is not impossible that this species was introduced to Europe with exotic plant material.

Psilocybe collybioides Singer and Smith

10. ***Psilocybe collybioides*** Singer and Smith, Mycologia 50: 141. 1958. (Figs. 10-11.)

Pileus 13-40 mm broad, at first campanulate and often soon varying toward convex, at maturity convex or retaining a more or less elevated umbo, eventually tending to become flattened and irregular, surface glabrous, viscid when moist, somewhat hygrophanous, when moist usually finely translucent striate and more sordid-pallid all over, faded light ochraceous brown (*13K 9*) with dingy pallid center, discoloring (where touched and on drying) from the center outward and finally reaching *bottle green* or *bayou*, often with a short sulcate margin.

Lamellae pallid to pure white, in some slightly brownish at maturity, close or subclose, more or less adnate, moderately broad to broad (e.g., 2.5 mm).

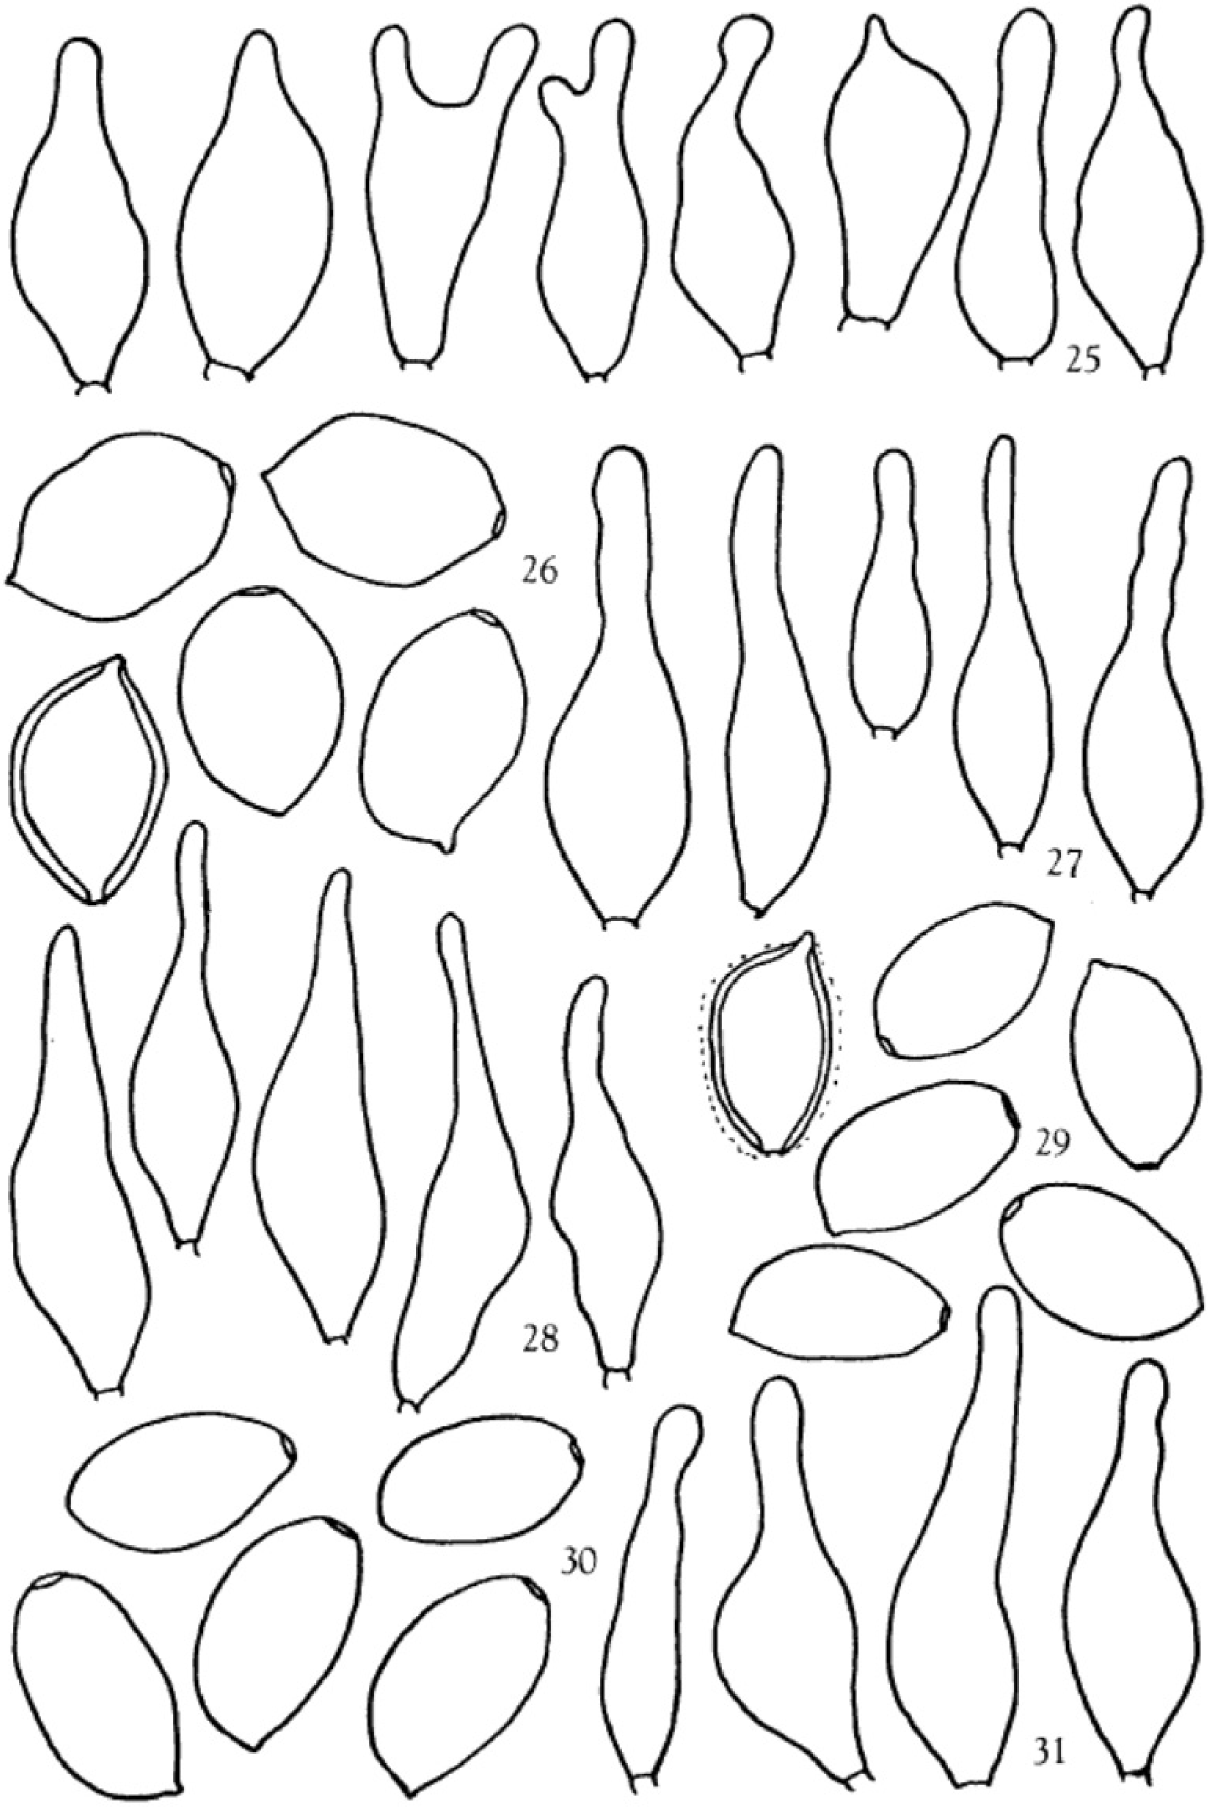
Stipe 30-70 x 1.5-4.5 mm, equal to slightly thickened downward, often twisted-contorted, curved, compressed, knotty or variously irregular, stuffed becoming hollow, white at first, often becoming cinnamon-brown from the base upward, at times remaining white or fading out to white again in age, when young silky fibrillose and sometimes sub-squamulose from the veil, later appressed finely fibrillose, apex fibrillose-pruinose; veil cortinate-fibrillose, white, fugacious; basal mycelium sometimes strigose, white, and forming white rhizomorphs.

Context white to pallid or in parts cinnamon, always discolored under the cuticle and in cortex of stipe, turning green to blue (*bottle green* or *bayou*) when injured, fleshy in pileus, somewhat tough in stipe; odor slightly farinaceous becoming spermatic.

Spores generally none, or few, typical of the *Strophariaceae*, about 10 x 6.5 µ (hymenophore nearly sterile or sterile); basidia not seen; pleurocystidia in form of cystidioles forming the hymenium, hyaline, some 24-32 x 7.3-9.5 µ, attenuate above and often with a rounded mucro, others more pseudoparaphysoid, vesiculose to broadly clavate, 14.5-23 x 9.3-13 µ; chrysocystidia none; cheilocystidia abundant, causing the gill edge to he heteromorphous, 17-23.5 x 8-9 µ, fusoid-ventricose with narrow (1.5-2 µ) extended neck and with obtuse to capitate (and then up to 3.5 µ diameter) tip; subhymenium consisting of irregular very small elements; hymenophoral trama regular, its hyphae with about 0.5 µ thick walls, without membrane-pigment; epicutis a pellicle consisting of loosely arranged gelatinized hyphae, hyaline in KOH; hypodermium of nearly non-pigmented hyphae, or in some a slight amount of wall incrustation (melleous) present, especially in young non-contorted carpophores; clamp connections present.

On dry slopes over loose gravel near *Alnus jorullensis* var. *spachii* and on various types of organic debris (humus, grass culms, semi-decomposed alder leaves, etc.) in semi-shade, gregarious, fruiting in the summer rainy season (February), Argentina, prov. Tucumán, Pre-Andine Sierras, Tafí del Valle, 2000 m altitude, *Singer T 1882*, TYPE (MICH).

The above collection was designated type in order to leave open the question of the identity of the North African species whose description follows, even though the latter and the type appear to be the same. If the North African species is not the same as ours it will have to be renamed because the epithet *cyanescens* is preoccupied in *Psilocybe*. The Argentine species described above has the appearance of a *Collybia*, hence the specific epithet proposed.



Figs. 25-31. 25-26: cheilocystidia and spores of *Psilocybe mexicana*. 27 and 29; cheilocystidia and spores of *P. silvatica*. 28 and 30: cheilocystidia and spores of *P. pelliculosa*. 31 : cheilocystidia of *P. aztecorum*.

Description of Maire's sterile to semi-sterile material from Algeria

The following description of *Hypholoma cyanescens* R. Maire, Bull. Soc. Mycol. Fr. 44: 51. 1928, refers to a North African species which we think probably identical with *P. collybioides*. This description is adapted from the original diagnosis. We have seen no specimens.

Pileus 15-30 mm broad, convex, then expanding, not umbonate, viscid and with a separable glutinous pellicle, hygrophanous, dingy ochraceous, faded pallescent, margin faintly striate or not striate.

Lamellae whitish becoming dingy and pallid ochraceous, finally light rufous-fuscous, close, thin, narrow (1.5-2.5 mm), arcuate, somewhat rounded behind and narrowly attached (rounded-adnexed), not intervenose, lamellulae attenuate, edges whitish pruinate.

Stipe 25-40 x 2-5 mm, subequal or slightly enlarged below, stuffed with a white silky medulla, eventually tubular, whitish, apex pruinose, innately fibrillose downward; cortina cobwebby, white, fugacious.

Context slightly fulvous, fulvous in the base of the stipe, faded pallescent, white in the stuffing of the stipe, bluing in all parts of trama on injury; odor raphanaceous; taste mild.

Spore deposit purple-brown.

Spores 10-12 x 5.5-6.5 µ, from 4-spored basidia, occasionally up to c. 20 x 7.5 µ from 2-spored basidia, ellipsoid, light fuscous brown, rather thick-walled, smooth, with a rounded to slightly attenuated apex furnished with a germ pore; basidia clavate, 4-spored, few 2-spored, 28-32 x 7-9 µ; pleurocystidia none or rare and similar to cheilocystidia; cheilocystidia 30-40 x 6-8 µ, fusiform with a subcylindric ampullaceous neck and an apex incrusted with calcium oxalate; subhymenium thin, ramose; gill trama regular, its elements 5-8 µ in diameter and rather long, interwoven.

Chemical characters: guaiac solution negative; NH_4OH negative.

Gregarious under *Cedrus atlantica*, fruiting from October until December. Algeria, Blida and La Chréa.

Description of fertile material referred to Hypholoma cyanescens by Malençon

The following description is translated and adapted from Malençon (8):

Pileus 15-35 mm broad, almost spheric to convex becoming campanulate to conic-campanulate, the margin finally spreading, viscid from a separable gelatinizing pellicle, naked, hygrophanous, ochraceous then amber yellow with a bister shade, finally dusky olive, bister, fading from the disc outward to yellowish white or dull stramineous ("as if it were gouachée"), in age at times disc leather color, translucent-striate half way to disc when moist, opaque when faded.

Lamellae pale argillaceous becoming more lilac-beige, eventually dark purple brown, thin, not close, narrow, ascending, free to slightly adnexed, with white fimbriate edges.

Stipe 50-70 x 2-3 mm, equal to a slightly thickened base, solid becoming fistulose with a slight silky stuffing, pruinose on apex, lower down with a thickish coating of silvery to yellowish appressed fibrils; cortina silvery white, fugacious; basal mycelium cottony white, agglutinating, long white rhizomorphs present.

Context watery, with an amber color tone, lower part of stipe amber, thick in disc of pileus, thin toward margin, rather rough in stipe, changing green to blue where injured; odor and taste none.

Spore deposit blackish purple fresh, blackish in the herbarium.

Spores (11-)11.25-13(-13.5) x 5.5-7 µ, most frequently 11.2-11.8 x 5.5-6.25 µ, almond shaped, smooth, thick-walled, violet in water mounts, yellow brown in NH_4OH, apical germ pore obliterated by a hyaline callus; basidia 30-35 x 8 µ, 4-spored, cylindric or constricted, sterigmata 5 µ long; cystidioles (?) piriform, 15-17 x 7.5-8.5 µ; pleurocystidia (other than cystidioles) none or similar to cheilocystidia and near gill edge;

cheilocystidia 30-40 x 6-8 µ, abundant (edge heteromorphous), ampullaceous and neck often incrusted with a spherical collar, walls hyaline; subhymenium cellular (?); hymenopodium of thinner more parallel hyphae than the hymenophoral trama proper which consists of broad hyphal cells narrowed at the septa; apex of stipe with numerous dermatocystidia similar to cheilocystidia; pellicle of pileus of interwoven gelatinized hyphae, with those of the extreme surface often diverticulate as in some *Mycenae*; hypodermium filamentose.

Often on small pieces of dead wood but also on the ground, fruiting from October until November in the *Cedretum* (*atlanticae*) and *Quercetum* (*ilicis*) above Azrou, Morocco.

In order to represent the facts as free from possible misinterpretation as we reasonably could, we have presented the data available on the collections made by each author. Experience with numerous sterile forms in the genus *Naematoloma* in North America has shown that in these the colors invariably have more yellow in pileus, lamellae, and stipe than do those of normally fertile carpophores, but that there is no correlated variation in spore size and shape. Hence, as long as these characters can be obtained from semi-sterile forms, they can be used in classifying collections. We do, however, believe that in interpreting differences in color, especially as the yellow pigments are concerned, it is best not to attempt fine distinctions between collections in situations such as this one. Also we cannot regard semi-sterility in itself as necessarily being a legitimate species character.

We believe that all of the material on which the descriptions presented here are based belongs in a single species. Spore characters are essentially the same, as are the characters of the cheilocystidia and lack of pleurocystidia. There may be some differences in odor and taste but in no case are the characters pronounced enough to be convincing in view of the small amounts of material tested.

Since the specific epithet *cyanescens* cannot be transferred to *Psilocybe* because of the existence of *P. cyanescens* Wakefield, we are describing the South American material as a new species and designating a type from that region. By doing this we do not prejudice the situation as far as future studies of the African populations are concerned. If some of the slight differences noted in the descriptions presented here are found to be important, adjustments in the classification can then be made. There is the possibility that Malençon's collections are con-specific with Miss Wakefield's *P. cyanescens*.

Psilocybe strictipes Singer & Smith

11. ***Psilocybe strictipes*** Singer & Smith, Mycologia 50: 141. 1958. (Figs. 12, 15, 50.)

Pileus 20-40 mm broad, when young campanulate to convex, becoming broadly convex to plane or with an elevated wavy margin in age, glabrous, viscid from a separable pellicle, margin striatulate when moist, hygrophanous, dull yellowish brown to olive brownish ("Isabella color"), fading to cinnamon buff on disc and pallid on margin, becoming dingy over all in age, where bruised staining greenish or bluish green.

Lamellae pallid becoming dark chocolate color from the spores, bluntly adnate to depressed-adnate, horizontal, narrow (4 mm in a 40 mm cap), close but not crowded, with three tiers of lamellulae.

Stipe 100-130 x 2-3 mm, straight, equal or slightly flared at apex, stuffed with a pallid brownish pith, staining brownish where outer fibrils have been removed, surface pallid from appressed fibrils, often zoned near apex from broken veil, with fibrils over lower half and strigose hairs at base, staining bluish green.

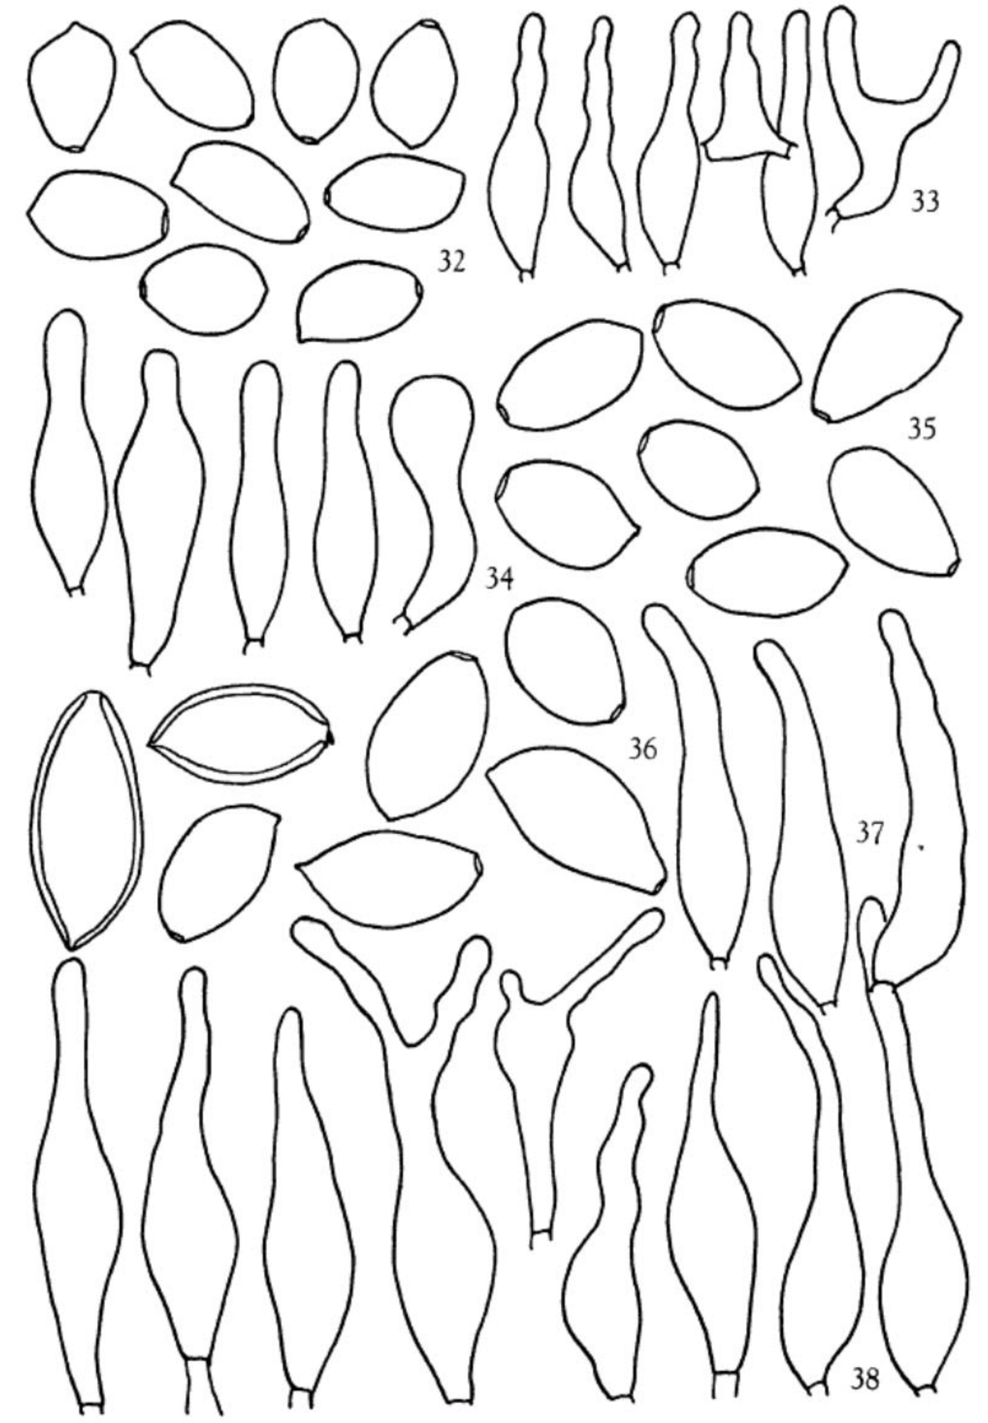
Context concolorous with surface in pileus, dingy brownish and cartilaginous in the cortex of the stipe; odor none; taste mild.

Spore deposit purplish.

Spores 9-12(-l2.7) x 5.5-6.5 µ, smooth, with a distinct apical germ pore, oblong in face view, slightly inequilateral in side view, sordid tawny in KOH; basidia 25-31 x 7-9 µ, 4-spored, clavate or subcylindric with a median constriction, projecting when sporulating; hymenium dull rusty brown to pale yellowish in sections revived in KOH; pleurocystidia none or only near gill edge and similar to the cheilocystidia; cheilocystidia 26-45 x 6-12 µ, abundant, causing gill edge to be heteromorphous, hyaline, ventricose below, subulate, attenuated gradually towards the subacute to obtuse tip; gill trama of enlarged cells pale sordid brownish to hyaline (paler than hymenium in KOH); epicutis a thick gelatinous pellicle of hyaline narrow (1.5-3.5 µ) hyphae; hypodermium of broad (3-10-18 µ), somewhat interwoven hyphae, pigmented but almost as pale as the flesh beneath, not incrusted; clamp connections readily demonstrated.

Subcespitose on wood of conifers and debris in coniferous and mixed woods, fruiting in October, Oregon, U.S.A.

Material studied: Oregon: near Welches, *Gruber & Smith 20248*, TYPE (MICH). Other specimens from the same general region: *Smith 24622, 24402* (MICH). (No. 202448, indicated as the number of the type in the original diagnosis, is erroneous.)



Figs. 32-38. 32-33: spores and cheilocystidia of *P. aggericola*. 34-35: cheilocystidia and spores of *P. muliercula*. 36-38: spores and cheilocystidia of *P. caerulipes*.

Psilocybe baeocystis Singer and Smith

12. ***Psilocybe baeocystis*** Singer and Smith, Mycologia 50: 141. 1958. (Figs. 13, 16.)

Pileus 14-54 mm broad, appearing umbonate when dried but conic when fresh and with incurved margin, finally expanding to convex or plane, viscid from a thin gelatinous pellicle, olive brown to buffy brown, when dried tending toward copper brown in the center, with a faintly striate margin when moist, finally with a greenish fringe around the margin and incoming greenish where touched.

Lamellae dark cinnamon or gray, also with faint purplish tints in some, eventually nearly "heliotrope gray," adnate to uncinate, subclose, edges whitish.

Stipe 50-70 x 2-3 mm, equal to subequal, stuffed with loose fibrils, with fine white fibrils on surface, white except for apex which is yellowish; veil present but inconspicuous.

Context concolorous or paler than surface in pileus, brown in stipe; odor and taste none.

Spore deposit "heliotrope gray."

Spores (8-) 10-13.3 x 6.3-7 µ (mostly 11-12 x 6.3-7 µ), terete or nearly so, with a broad distinct germ pore, deep olive to dingy brownish olive-yellow in KOH, smooth, wall very thick and complex, with a suprahilar depression or applanation; basidia 20-30 x 7-9 µ, 4-spored, hyaline to stramineous; pleurocystidia none; cheilocystidia 20-30(-36) x 4.2-5.7 µ, ampullaceous with a long thin neck (1.2-1.5 µ diameter) and subacute apex, or more often ventricose below or in middle but then pedicellate and tapered to an acute apex, hyaline, causing gill edge to be heteromorphous; subhymenium a rather broad and irregular layer of small versiform elements, slightly pigmented; hymenopodium a thin filamentous layer, regular, not as well separated as in some other species; gill trama hyaline, regular, with a slightly and indistinctly differentiated mediostratum and this flanked by parallel hyphae on either side, progressively more pigmented in the third of the trama closest to the pileus trama; epicutis a very thick hyaline gelatinous layer of narrow loosely arranged hyphae; hypodermium weakly to strongly pigmented, consisting of compactly parallel horizontal hyphae broader than those of the epicutis; clamp connections regularly present.

On decaying "peat moss" (actually apparently a mixture used instead of pure *Sphagnum*) by a green house, Eugene, Oregon, U.S.A., *F. P. Sipe*, 11-1-1945, TYPE (MICH).

This is somewhat similar to *P. strictipes* and may be confused with it, but differs in the size and shape of the cheilocystidia, which are reminiscent of those of *P. caerulipes*.

Stirps Caerulescens

13. ***Psilocybe caerulescens*** Murr., Mycologia 15: 20. 1923 (Figs. 18, 19, 21-24, 46, 48.)
    Psilocybe macatecorum Heim, C. R. Acad. Sc. 242: 1392. 1956, nom. subnud.
    Psilocybe caerulescens var. *mazatecorum* Heim, Rev. de Mycol. 22: 78. 1957.

Pileus 20-88 mm broad, at first obtusely campanulate, becoming convex with a decurved margin, at times slightly umbilicate or with a small umbo, rarely becoming irregular and almost plane or shallowly depressed in age, almost black or very deep olive-umber at first, becoming paler and olive tinge often disappearing, in age often rather pale colored (near *aztec*), umbo either darker than marginal area or at times paler, hygrophanous, fading gradually to ochraceous from disc outwards, sometimes assuming chestnut or fulvous colors in the moist areas while still fading (see illustrations by Wasson), and these at times persistent in the faded specimens, a brownish shade often pervading the disc, glabrous, smooth, slightly viscid to lubricous, short striate by translucence in smaller caps or striate half way to disc in large ones when moist, opaque when faded; veil usually fugacious on pileus, but sometimes more persistently white appendiculate.

Lamellae mostly light avellaneous gray or argillaceous, only in age reaching sepia, sinuate-adnate to bluntly adnate, close to subclose, broad, edge slightly white fringed.

Stipe 40-122 x 2-10 mm, typically equal, hollow, glassy-white to sordid although at first always with a continuous white velutinous soft covering which soon breaks up into a marbled to flocculose covering on a sordid ground color, the apex pallid fibrillose, glabrescent; basal mycelium white, occasionally developing some white rhizomorphs which at times turn blue when injured; veil thin and at first appearing cortinoid, pure white, often forming a ring for a very short time in young or nearly mature specimens, not distinctly bluing.

Context of pileus whitish to sordid or even tawny to fulvous, sometimes dark brown in upper portion of pileus, fleshy, somewhat fibrous-hard in stipe, blue when injured; odor strongly farinaceous; taste astringent.

Spore deposit deep purple fuscous, sepia.

Spores (6-)6.3-7.7 (-8) x 5-6 x 3.5-5 µ, compressed, 0.5-1 µ narrower in side than in face view, varying from subrhombic with rounded angles to ovate in face view, and from elliptic to inequilateral in side view, deep yellowish brown in KOH, smooth, with a broad germ pore, wall thick and compound as revived in KOH, showing a rusty line along the endosporium, without a suprahilar depression but at times with a small applanation; basidia (12-) 14-21 x 4.9-7 µ, 4-spored, rarely 2-spored; pleurocystidia none except for some permanently sterile basidioles (?) or a few cells resembling the cheilocystidia; cheilocystidia 15-20(-26) x (3-)4-5.5(-6) µ, hyaline, fusoid to fusoid-ampullaceous, the apex acute to slightly enlarged, neck sometimes flexuous to filamentous and 1.5-2 µ in diameter; subhymenium a narrow layer of irregular short elements, melleous to hyaline as revived in NH_4OH; hymenopodium hyaline, consisting of parallel filamentous hyphae; the hymenophoral trama proper consisting of a lateral stratum of broad (7-11 µ diameter) hyaline hyphae accompanying the mediostratum on both sides, and the mediostratum consisting of a mixture of broad and narrow (2.5-3 µ) hyphae, walls of all cells 0.3-0.4 µ thick; epicutis well developed, consisting of thin filamentous hyphae occasionally with an upturned terminal cell, slightly gelatinized; hypodermium denser than the flesh beneath and more deeply colored; hyphae of the context of the pileus short and voluminous, cell walls c. 0.7 µ or less thick, deep ocher brown from incrusting membrane-pigment; clamp connections present.

Chemical characters: guaiac solution, bluing on white portions of context.

Gregarious to caespitose, rarely solitary on soil or on sugar cane mulch, mostly in shaded places or on rich earth which has recently been moved or altered, fruiting in summer, during the rainy season. Southern United States (Alabama) and Mexico (Oaxaca).

Material studied: U.S.A.: Ala., Montgomery, TYPE (NY). Mexico: Oaxaca, Huautla de Jiménez, *R. Heim* (as *P. caerulescens* var. *mazatecorum* Heim), (NY); *Singer M 1513* (MICH).

Illustrations: V. P. & R. G. Wasson, Mushrooms Russia and History 2: *pl. 40, fig. 3* (poor); *Life*, May 13, 1957, p. [107], *fig. at upper right*.

Heim first described this fungus as a new species and then, after receiving a letter from Smith suggesting that the species was the same as *P. caerulescens* Murr., he apparently changed his mind and referred to it as *P. caerulescens* var. *mazatecorum* but gave no immediate critical account of how var. *mazatecorum* was actually different from the type variety. There may be a difference in the taste since that was indicated as mild in the type collection, but until the recent interest in hallucinogenic fungi this species remained known almost entirely from the type collection made by R. P. Burke of Montgomery, Alabama, who wrote "no characteristic taste." It is possible that Burke did not regard a slight astringent taste as distinctive, or that in merely tasting the raw specimens he did not chew the material long enough to bring out the true flavor.

The character of the veil's being more developed in var. *mazatecorum* than in var. *caerulescens*, as Heim emphasized in his Latin description, is dubious because from the description of Burke's collection it is likely that his notes referred to mature specimens and the fact that no veil is mentioned cannot be regarded as conclusive. Hence, there seems to be no way to prove these points except by continued collecting and observing, both in the southern United States and Mexico, to determine eventually the range of variability.

Psilocybe aggericola Singer & Smith

14. ***Psilocybe aggericola*** Singer & Smith, Mycologia 50: 142. 1958. (Figs. 32-33.)

Pileus 20-40 mm broad when young, campanulate, then conic campanulate or convex, disc at first umbonate, and with a slight umbilicus in the umbo, later with a pronounced central papilla, margin incurved at first but soon straight, strongly hygrophanous and translucent-striate over outer half when moist, estriate when faded, glabrous and naked, except rarely with vestiges of the veil along the margin, colors light olive brown or brown with a darker disc (*oak, Sudan br*. young, disc sometimes *burnt umber*, becoming khaki to *Isabella color*, with a *tortoise* colored disc) fading to a dull deep yellow tone (*9 J 6*) when young, to pale chamois (*11 F 4*) when old, tending to blacken when drying.

Lamellae narrowly and rather deeply sinuate to adnexed, close or subclose, moderately broad or rather broad and broadest towards the stipe, dingy (olive) brown (*bamboo* to *stag*), trama staining blue where exposed, edges white and entire.

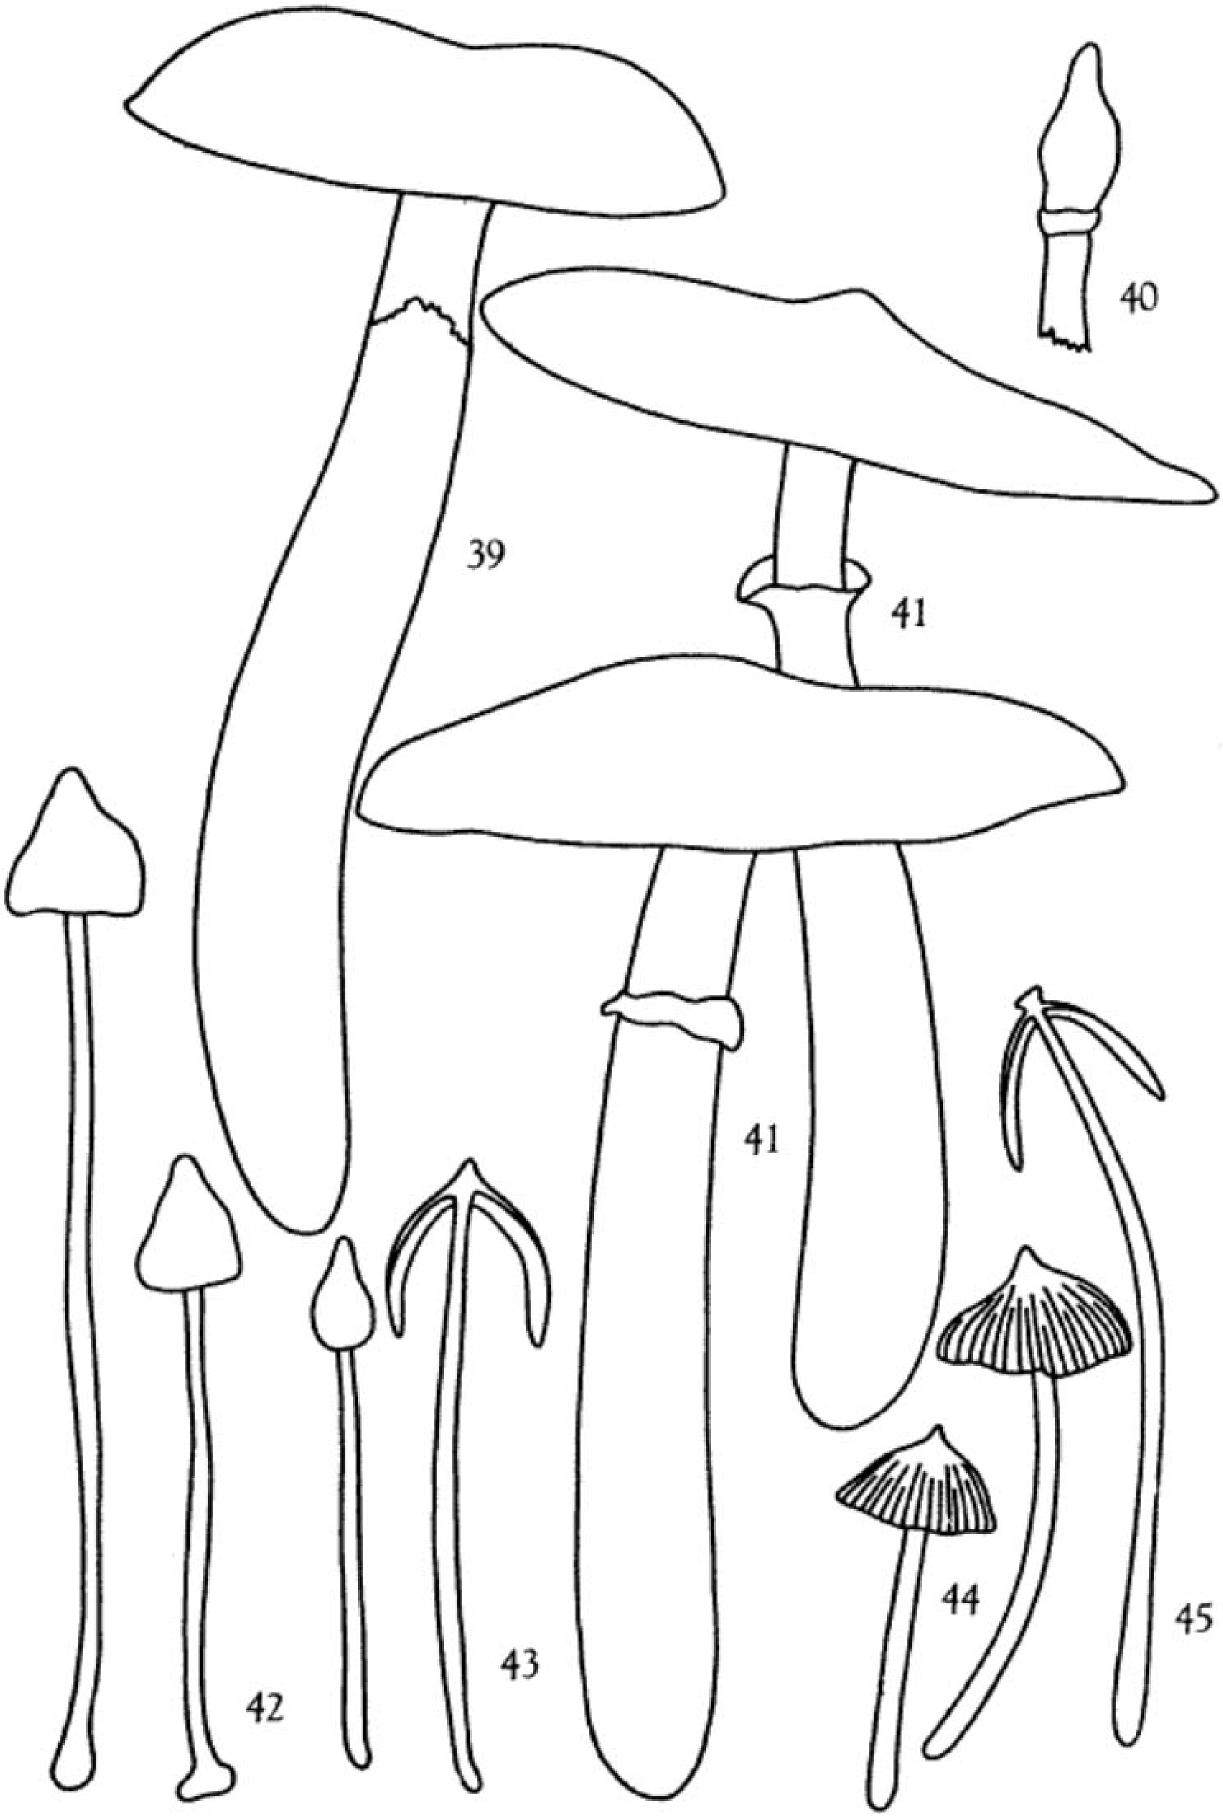
Stipe 25-80 x 6-13 mm, later 2.5-6 mm, tapering upward or finally nearly equal, light ochraceous (*Leghorn*) above, later becoming somewhat burnt umber, dingy ocher (*maple*) downward and finally coffee-with-milk color (*Mosul*) in lower half, turning blackish in drying, with a sordid cream to pallid floccose-fibrillose covering which is very conspicuous in young material though fugacious in the upper half (persistent in the lower half) of adult stipes, bluing where injured or on handling, the base white mycelioid; veil forming a fugacious, very narrow annular belt at apex but annulus disappearing at maturity.

Context rather firm at first, more fragile in age, not tough in stipe, light ochraceous (*Leghorn*) becoming coffee-with-milk color (*Mosul*), and turning blue (*Quaker blue*, *Arctic*, finally reaching *Rigi blue* in dried condition) when either pileus or stipe is bruised; odor none.

Spore deposit deep purple fuscous.

Spores 6.2-8 x 4-5.2 x 3.6-4.5 µ, usually 6.7-7.3 x 4-4.5 x 3.7-4.2 µ, somewhat but little compressed or almost terete (usually 0.3-0.4 µ broader in face than in side view), slightly inequilateral in side view, elliptic-ovate to rarely rhombic in face view, with a broad germ pore, dingy yellow brown in KOH, smooth; basidia (12.5-) 14.5-20.5 x 4.2-5.5(-7) µ, 4-spored to rarely 2-spored, hyaline or nearly so, clavate to broadest below the apex, basidioles vesiculose-clavate; pleurocystidia 20-32 x 6-9 µ, originating in the subhymenium, contents homogeneous (not protoplasmatic), with a thin colorless resinous incrustation which renders them opaque, varying from clavate to fusoid or ventricose-ampullaceous or constricted in the middle, often with lateral outgrowths or apical nose-like appendages but these lacking in some preparations; cheilocystidia 20-25(-29) x (3.5-)5-5.5(-8.2) µ, usually somewhat ventricose below, upper portion lanceolate narrowed in one or two stages to an acute apex, entirely hyaline and transparent, thin-walled, non-incrusted, causing the gill edge to be heteromorphous; subhymenium when revived in NH_4OH often strongly green from a membrane-pigment, later honey yellow, consisting of a thin layer or irregularly arranged hyphal cells of various shapes; gill trama consisting of elongated subparallel hyphae of variable width and having walls 0.5-0.7 µ thick, the mediostratum not sharply differentiated from the hymenopodium and lateral stratum; epicutis of pileus a thin and not sharply differentiated layer of hyaline hyphae, the hyphae not much gelatinized, when revived in NH_4OH, freshly dried material appearing greenish but later losing all color; hypodermium composed of elements which show very variable shape but not isodiameteric, brownish melleous as revived but hyphal walls not incrusted; clamp connections present.

Chemical characters: formalin on the flesh immediately brownish, not bluing; $FeSO_4$ on flesh, causing a bluish gray ring to appear around a brown spot.



Figs. 39-45. 39: *P. candidipes*. 40-41: *P. cubensis*. 42: *P. pelliculosa*. 43: *P. mexicana*. 44-45: *P. yungensis* (44 = var. *acutopapillata*, 45 = var. *yungensis*).

Singly or in small cespitose groups of two or three on rich soil along dammed-up earth of the road, outside the forest in subtropical vegetation, fruiting in spring. Argentina, prov. Tucumán, road to Tafí dell Valle near Monumento al Indio, 900-1000 m altitude, *R. Singer T 760*, 11-13-1949 (MICH).

The opaque pleurocystidia distinguish this species from all similar ones.

Psilocybe candidipes Singer & Smith

15. ***Psilocybe candidipes*** Singer & Smith, Mycologia 50: 141. 1958. (Figs. 14, 17, 20, 39.)

Pileus 50-55 mm broad, convex with shallowly depressed disc, always obtuse at first, smooth and glabrous, slightly viscid, when moist translucent-striate over the marginal third, sordid buff to dull buff, hygrophanous, fading from the disc outward, pale buff to whitish when faded, readily staining blue when touched.

Lamellae pale avellaneous to avellaneous-gray, sinuate-adnate, rather broad, fairly close to subdistant.

Stipe about 100 mm long, 7-12 mm thick, hollow, nearly equal, readily staining blue, strongly scabrous-strigose near base, and this coating ascending up to mid-portion, increasingly white floccose upward to the annular zone left by the broken veil; veil white, soft, annular, remnants fugacious, but floccons below annular zone rather persistent, readily staining blue where injured.

Context whitish to dingy white, fleshy in pileus, fibrous-hard in the stipe; odor weakly but distinctively farinaceous.

Spores 6.7-7.7 x 3.5-3.8 µ, terete or nearly so, oblong-ellipsoid to ovoid, smooth, wall complex but relatively thin (0.7 µ), both episporium and endosporium differentiated, with a distinct apical germ pore; basidia 4-spored, 13.5-21 x 3.5-6.3 µ (mostly 4-5 µ broad), clavate, not opalescent; pleurocystidia present only as cystidioles, ventricose-submucronate to fusoid-clavate, body of cell often opalescent but neck emerging and non-opalescent, 21-24 x 5-7 µ; cheilocystidia very numerous, lanceolate-fusoid to subulate, hyaline, 18-27 x 3.5-6 µ, upper part narrowed to 1.5 µ or less in diameter, acute to subacute; subhymenium melleous to brown (browner near cap trama), consisting of very small elements often appearing cellular in sections but in reality irregular in shape; gill trama regular, hyaline, in the poorly differentiated mediostratum melleous-hyaline, hyphae not markedly enlarged; epicutis well developed, of only slightly gelatinized narrow (1.3-3.3 µ) hyphae, near surface often giving rise to a cystidioid end-cell which is not gelatinous; velar floccons of stipe everywhere consisting of very irregularly shaped cells of various sizes either inflated or filamentous and strongly interwoven, frequently cystidioid cells arising from the surface hyphae of the velar material, these c. 20 x 5 µ and ampullaceous, apex 2 µ broad; clamp connections present.

Chemical characters: Several chemical substances accelerate and augment the bluing, especially guaiac solution.

On earth, cespitose, among fallen leaves of *Coffea* and *Inga* along irrigation ditches in plantations. Mexico, Oaxaca, Huautla de Jiménez, 1550 m altitude, *R. Singer M 1514*, 7-10-1957, TYPE (MICH).

The small terete spores, strong tendency to turn blue, and copious veil are an interesting set of characters in this genus. The strong development of the veil is a valid additional argument for including the stirps *Cubensis* in this genus. Weight is added to this argument by the fact that in *P. cubensis* the same kind of dermatocystidia are often found on veil and pileus. The two, of course, differ sharply in spore characters.

The young hymenium, typically hymenium just beginning to sporulate, is very interesting in view of the bluing phenomenon. The basidia and basidioles are incrusted with blue granules. The young cystidioles (obviously formed earlier in the development of the hymenium) are not. Does this mean that the early development of these cells did not include the production of the enzyme that causes the formation of the blue pigment? Also, does it prove that those cells which are destined to remain sterile are differentiated physiologically before morphological differences become evident?

Psilocybe zapotecorum Heim

16. ***Psilocybe zapotecorum*** Heim, Rev. de Mycol. 22: 77. 1957.

Pileus 60-110 mm broad, campanulate becoming obtusely umbonate to strongly mammillate but always twisted, asymmetric, most variable in shape, margin at first white punctate with the veil remnants, (soon) glabrous, color varying from ochraceous citrine to purple-brown-black (Klingcksieck et Valette no. 45) with ochraceous-melleous tones, with dark violet stripes and gradually becoming violet black on margin, apparently hygrophanous and dingy melleous when faded.

Lamellae rather close, with sinous edges, adnexed-emarginate, not very broad, violet-purple.

Stipe 100-200 mm long, 10-20 mm broad at base, hollow, very fibrous, hard, elastic, often contorted, outer layer of cortex brownish, ochraceous toward the interior and with a central soft white bluing pith, (surface) fibrillose.

Context at first brown-rufous in cortex of stipe, yellow in central portion, entirely and quickly bluing; odor farinaceous; taste astringent.

Spore deposit brown-purple.

Spores 6-8.8 x 3.5-5 x 3-4 µ (Heim 1957), rather bright yellow revived in KOH, somewhat compressed, with a broad apical germ pore; cheilocystidia fusoid, with a filiform neck which is covered by a substance stained by dyes (such as "bleu lactique").

On swamp soil, Yaitepec and San Agustin de Loxicha, Oaxaca, Mexico. Used as hallucinogen by the Chatino and Zapotec Indians, known as "mbey san" or "piule de barda" (according to Heim).

Illustration: *Life*, May 13, 1957, p. [107], *fig. at upper left*.

Material studied: None. The above incomplete description is based on fragmentary data and a Latin diagnosis furnished by Heim. Probably there are specimens at Paris.

The habitat is not particularly strange for a *Psilocybe* as far as North American members of the genus are concerned; therefore, it is rather a surprise to find that Heim considered it so. A relatively tough context of the stipe is likewise not unusual in the genus, and it may only be relatively more so in *P. zapotecorum*. Nevertheless, it is possible that this species does not belong with the preceding species. We do not wish to judge its final relationships without having had a chance to study specimens.

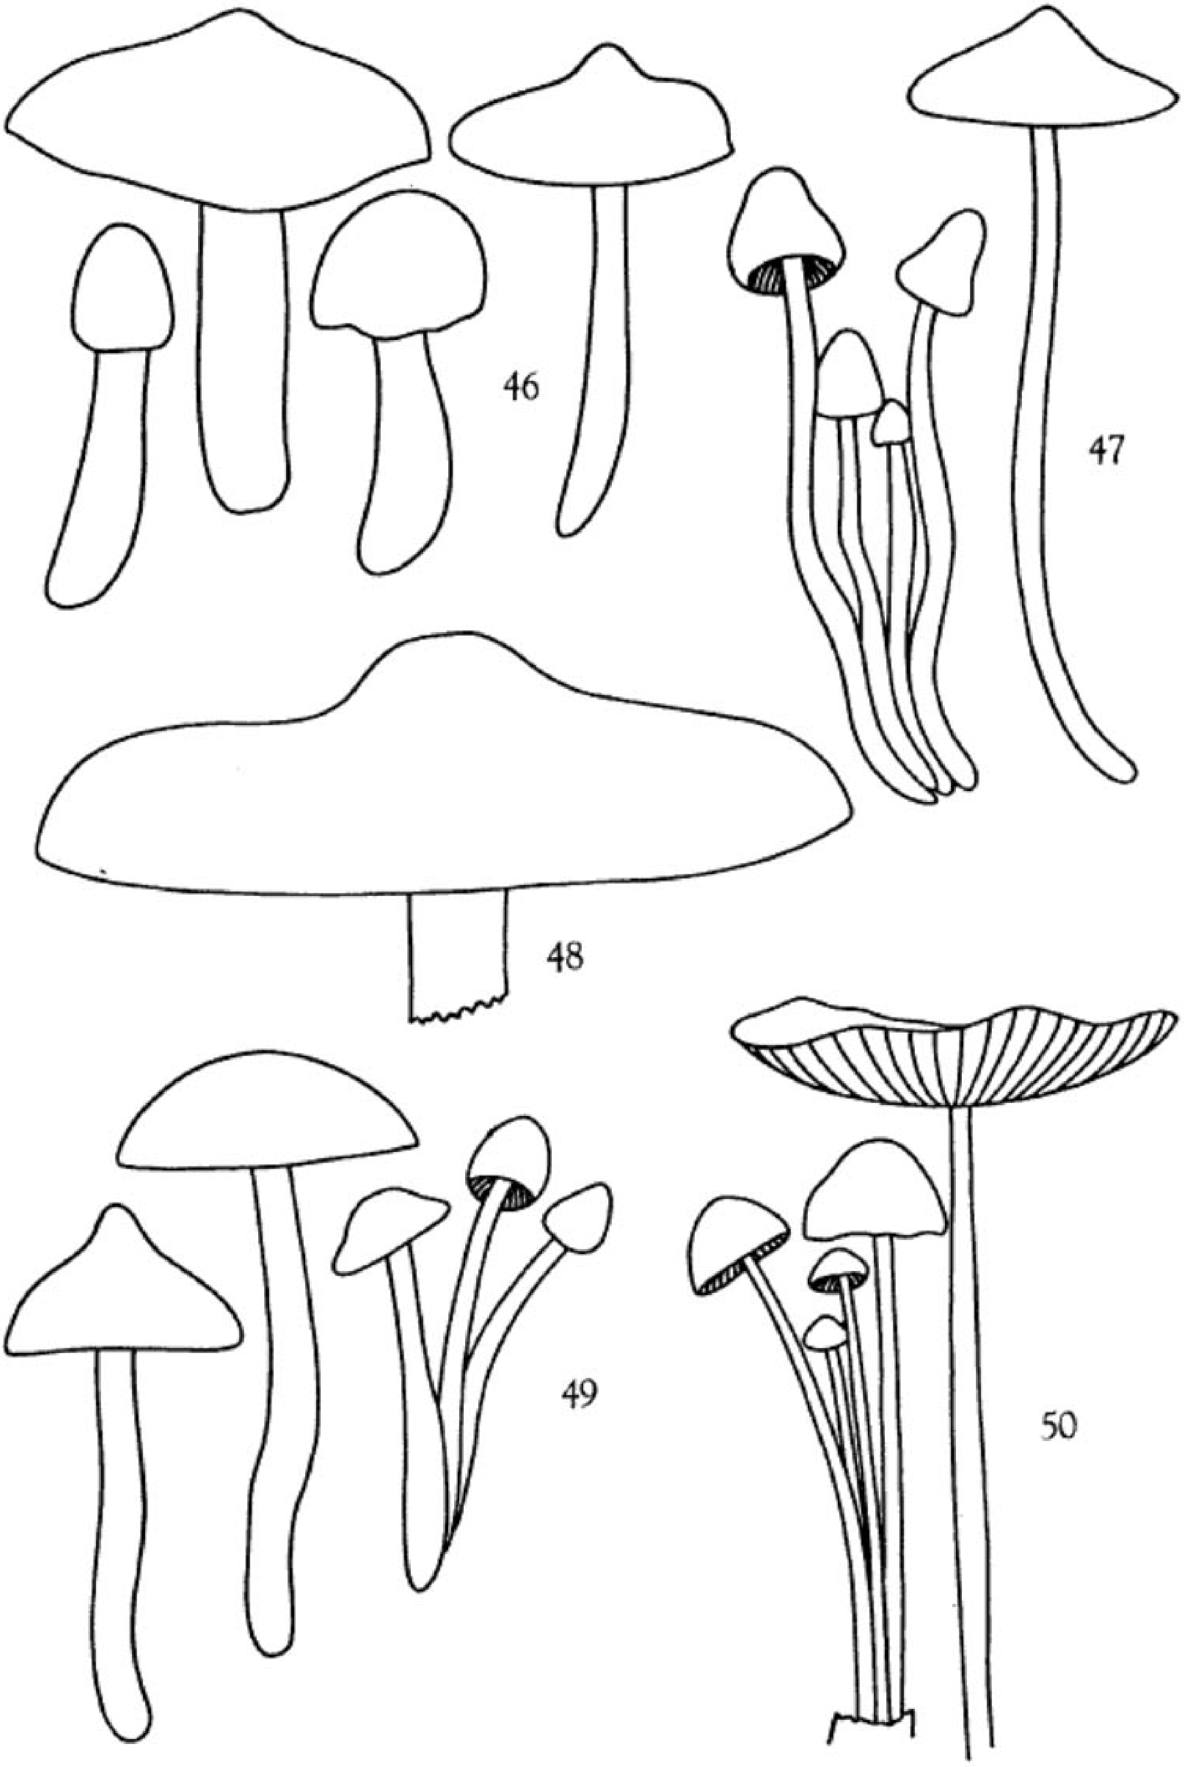
Stirps Caerulipes

Psilocybe Muliercula Singer & Smith

17. ***Psilocybe muliercula*** Singer & Smith, Mycologia 50: 142. 1958. (Figs. 34-35, 49.)

Pileus 20-35 mm broad or more, campanulate then convex, eventually often applanate in a zone between the umbo or papilla and the somewhat decurved marginal area, more or less umbonate, rarely papillate, fulvous brown, hygrophanous, fading out to a pale ocher tone, glabrous, not viscid, marginal area translucent-striate (up to about half way to disc) when moist, slightly sulcate at times, naked.

Lamellae fuscous-sepia, almost narrow, ascendant to subhorizontal, sinuate-adnate, often seceding, with pallid edges.



Figs. 46-50. 46 and 48: *P. caerulescens*. 47: *P. caerulipes*. 49: *P. muliercula*. 50: *P. strictipes*.

Stipe (30-) 40-100 x 2-7 mm, equal or tapering upwards, becoming hollow, sordid flesh-colored-whitish, becoming concolorous with the pileus especially below, staining blue where touched and blue stains eventually very deeply colored, smooth, more or less glabrous and naked; veil very sparse and all traces of it obliterated in mature specimens.

Context tending to turn blue where injured; odor farinaceous; taste in dried specimens not distinctive.

Spores (6-)7-8(-10) x 4.2-4.8(-5)x 3.9-4.7 µ, either terete or up to 0.3 broader in face view than in side view, elliptic to elliptic-ovate in either view, rarely subrhomboid with rounded angles in face view, sometimes ventricose-fusoid (shaped like a bolete spore) in side view, with a distinct apical germ pore, dark yellowish brown in KOH; basidia 16.5-21 x 5-5.5 µ, 4-spored; pleurocystidia none; cheilocystidia 12-23 x 3-5.5 µ, hyaline, subulate to subulate-ampullaceous, apex obtuse and sometimes subcapitate, more often subacute or acute, neck at apex 1.5-2 µ in diameter; subhymenium a thin layer, irregular, of small elements; gill trama regular, walls of hyphae up to 1.5 µ thick (thick-walled for the genus); epicutis a well developed layer of hyaline filamentous hyphae but not strongly gelatinized; hypodermium well colored by membranal pigment often incrusting the walls of the hyphae, the latter arranged into a compact layer or a cutis; hyphae of context and hypodermium with thickened (about 1.5 µ) walls; clamp connections present.

Solitary or in small clusters on earth along ravines of a pine-covered (*Pinus pseudostrobus*) mountain at about 3000 m elevation; fruiting in late August and September, rarely before. Known only from the slopes of Cerro Toluca (Mexico).

Material studied: Mexico, purchased at the market of Tenango del Valle (Toluca Valley), September 30, 1956, *T. Herrera* (MICH, MEX); September 1957, *G. Guzman* (MICH, MEX); purchased at Piedras Blancas, Cerro Toluca, July 30, 1957, *R. Singer M 1011*, TYPE (MICH). - There must be material of this at Paris since it was sent by T. Herrera to Heim, purchased at the same place and apparently identical with material earlier purchased in Tenango by the Wasson group and determined as *P. mexicana* var. *brevispora*.

This species is quite different from all other known species, particularly from *P. mexicana* which has larger spores and a more typically *P. semilanceata*-like habit.

Psilocybe caerulipes (Peck) Sacc.

18. ***Psilocybe caerulipes*** (Peck) Sacc., Syll. Fung. 5: 1051. 1887. (Figs. 36-38, 47.)
    Agaricus caerulipes Peck, Ann. Rep. N. Y. State Mus. 38: 89. 1885.

Pileus 10-35 mm broad, when young obtusely conic to convex and with an incurved margin, becoming broadly convex to plane or retaining a slight umbo, at times quite irregular, surface glabrous, viscid, soon dry and shining, closely translucent-striatulate and watery cinnamon brown to dingy "Sayal brown" fresh, hygrophanous and soon fading to dingy ochraceous buff or cinnamon buff, sordid alutaceous in age and often with greenish stains along the margin or with a greenish tinge overall.

Lamellae sordid brown when young, becoming rusty cinnamon, close or crowded, narrow, adnate or arcuate-adnate or with a decurrent tooth, edges whitish and slightly fimbriate.

Stipe 30-60 mm long, 2-3 mm thick at apex, equal or slightly enlarged downwards, stuffed with a pith but becoming tubular or hollow, the pith fairly persistent, surface pruinose at or near the apex, downward appressedly white to grayish fibrillose, usually staining greenish blue where handled, whitish to buff at first, especially above, pallid to bluish when dried, lower part often dingy brown in age; veil whitish, thin, forming an evanescent superior fibrillose zone; basal mycelium white.

Context in pileus thin and pliant, in stipe tough, in both becoming bluish when injured; odor none; taste farinaceous.

Spore deposit very dark purple brown.

Spores 7-9.8 x 4-5.3 (-5.7) x 4-5.1 µ, usually 8-8.5 x 4.4-5 µ, but those from 2-spored basidia 10-11.2(-12) x 5.7 µ, generally terete, only a small minority very slightly broader in face than in side view, ellipsoid, or elliptic in face view and inequilateral in side view, pale tawny to olive fuscous in KOH, truncate with an apical pore, smooth; basidia 15-28 x 5.2-7.5 µ, either all 4-spored, or some 2-spored, often constricted in mid-portion, hyaline in KOH; pleurocystidia none, or present only near gill edge, and then similar to cheilocystidia; cheilocystidia forming a broad sterile band at gill edge (which is heteromorphous), 18-35 x 4.2-6.7 µ, hyaline, with homogeneous contents, narrowly fusoid-ventricose, subulate, or ampullaceous, neck 1-2.2 µ broad and, if ampullaceous, 7-20 µ long, the tip sometimes slightly thickened to almost subcapitate (1.7-2.2 µ diameter), otherwise acute to obtuse, sometimes bifurcate; subhymenium seemingly cellular, but consisting of very irregularly shaped generally rather short very small elements, stramineous-melleous; hymenopodium of axial filamentous light stramineous-melleous hyphae 2-6.5 µ in diameter; gill trama not clearly differentiated in mediostratum and lateral stratum, regular, consisting of elongated hyphae 6-24 µ thick with 0.7-1.5 µ thick walls, melleous hyaline varying to pale brownish (in KOH); epicutis a gelatinous pellicle, not very broad, consisting of 2-4.5 µ thick hyaline (rare individual hyphae sometimes stramineous) filamentous hyphae which are loosely arranged; dermatocystidia none; hypodermium more irregular than epicutis, forming a cutis of compactly arranged short hyphal cells with brownish walls, but without any conspicuous incrusting pigment, hyphae 6-12 µ in diameter; this layer gradually merging below into the paler interwoven floccose trama of the pileus; clamp connections present.

Solitary or cespitose on debris of hardwood trees, especially *Betula* and *Acer* but also on their logs rotting on the ground. It fruits during the summer, more rarely in fall in the eastern and mid-western states of the U.S.A. and in Canada (Ontario), south to North Carolina.

Material studied: Canada, Ontario: Petawawa Exp. Forest, *Smith 26312* (MICH). U.S.A., Maine: near Guerette, *Bigelow 3531* (MICH). New York: Catlin Lake, Adirondack Mts., *Smith 219* (MICH); *C. H. Peck*, TYPE (NYS, NY). North Carolina: Indian Creek, Great Smoky Mts., *Hesler 10166* (MICH); *Smith & Hesler 17415* (MICH). Flat Creek, *Smith 10586* (MICH). Ohio: Cleveland, *Walters 186* (MICH). Tennessee: Grassy Patch, Great Smoky Mts. Nat. Park, *Smith 10545* (MICH). Michigan: Pontiac, *Smith 7268* (MICH); common around Pellston, Mackinaw City, *Smith 22186, 23459, 23460, 32893, 33648, 33824, 33825, 33933, 35872, 42103, 43053* (all MICH); *Thiers 3523* (MICH); Taquamenon Falls State Park, *Smith 36916, 37181, 37428, 39442, 41656, 41721, 41722, 41985, 41988, 42235, 49910, 49934, 49935, 49936, 49948, 49952, 49967, 50312; Thiers 3214* (all MICH).

The blue to greenish stains may be slow in developing but they usually show in a few hours.

Introduction

Fungi are strongly connected with the indigenous cultures in Mesoamerica. Fungi have been used in rituals; for medical purposes; or as food, as observed in the Mazatec, Nahuatl, Purepecha, Raramuris, and Zapotec cultures, among others in Mexico (Heim and Wasson 1958; Guzmán 1984, 1997; Lowy 1972a, 1974, 1977; Mapes, Guzmán, and Caballero 1981; Sahagún 1569-1582; Schultes and Hofmann 1979; Wasson and Wasson 1957; Wasson 1980). However, the information available is often sketchy because, at the beginning of the Spanish Colony following the Conquest, the indigenous cultures were languishing to extirpate their religious ceremonies (Lowy 1972b; Wasson 1980). The work of Sahagún (1569-1582), with his Magliabecchiano and Florentino Codices, is a good expression of the Nahuatl Culture concerning the knowledge of fungi. In the Magliabecchiano Codex, for instance, it is possible to see an Aztec eating a sacred mushroom with a personage at his back. For the Catholic Church, this personage is the devil; but, for the Indians, it is the god of the mushroom, Teonanácatl, who takes the Indian to his sacred and hallucinogenic world (Heim and Wasson 1958; Guzmán 1984; Wasson and Wasson 1957; Wasson 1980).

Wasson (1980) observed that we know virtually nothing about the fungi of the Maya Culture despite its great interest. Considered that the Maya area encompasses the whole of the Yucatán Peninsula; almost all of the Mexican states of Chiapas and Tabasco; and the Central American countries of Guatemala, Belize, El Salvador, and Honduras, the extent of the problem is apparent. The lack of information is not due to the absence of fungi use among the Maya, but to the great destruction that the Spanish Conquest inflicted on Maya Culture. Diego de Landa (1560) freely admitted that he burned codices and destroyed numerous idols in Yucatán; in his defense, de Landa stated that their destruction was necessary because those things contained nothing but superstitions and devils (Lowy 1972a, b; Wasson 1980). There are, however, many studies on the Maya Culture. In 1990, for example, an international symposium was held at Wakayama University in Japan; the main subject of this symposium was the Maya Culture (Guzmán 1992; Miyanishi 1992). Sadly, numerous mushroom stones and a few codices are the only information that we have on the culture of fungi among the past Maya Culture. Although we have evidence of the use of fungi as food or medicine in the Maya region, it seems that the practice of using ceremonial fungi has long since disappeared.

This paper summarizes the available information on mushroom use among the Maya, both in the past and present. This work is divided into three sections: (1) an historical examination of what we know about past Maya fungi use; (2) an overview of current mycological and ethnomycological studies in the Maya region; and (3) the first results of the fungi inventory at El Edén Ecological Reserve, which are currently being carried out.

Knowledge in the past

In spite of the destruction effected by de Landa (1560) in Yucatán, Lowy (1972a, b) noted that it is still possible to study the numerous mushroom stones and four important codices (i.e., Madrid, Paris, Dresden, and Galindo) remaining from the Maya Culture. The Galindo Codex was named by Lowy after he found it in the house of Mr. José Galindo (now deceased), a Guatemalan Indian in Huehuetenango.

Lowy (1972a, b) deduced that the Galindo Codex is a copy of the Madrid Codex after observing a similar image in both codices, in which an Indian painted in black is seen making an offering to an important seated personage. According to Lowy, the special object in the Indian's right hand is a stylized fruit body of *Amanita muscaria* (L. : Fr.) Hook., with typical wart-like patches on the cap. Lowy based his interpretation on the fact that this mushroom is now common in pine forests in both Guatemala and Chiapas, where it is surrounded in some mystery for the Indians. At present, they call this mushroom by the common Quiche names of "kaquiljá" (or "thunderbolt") and "itzel ocox" (or "evil mushroom").

Lowy (1974) noted the connection between the Thunderbolt Legend and *A. muscaria*. According to him, the Indians in Guatemala and Chiapas link this fungus with the thunderbolt because of its strong, rare power (the next section, however, presents another interpretation of the fungus and its relationship to the Thunderbolt Legend). Lowy (1974) also observed that the common name "yuyo" (from the name of a red common wild fruit) was applied both to the edible *Amanita caesarea* (Scop. : Fr.) Grev. as well as the poisonous *A. muscaria*; the latter is also called "yuyo del rayo" or "yuyo del trueno" ("rayo" and "trueno" mean thunderbolt). Guzmán and Ramírez-Guillén (2001) found that *A. caesarea* in Chiapas is a complex of four species: *A. jacksonii* Pomerleau, *A. laurae* Guzmán and Ramírez-Guillén, *A. tullossii* Guzmán and Ramírez-Guillén, and *A. yema* Guzmán and Ramírez-Guillén - all of them named "yuyo." *A. caesarea* s. str. is confined only to the central and northern portions of Mexico.

It seems that the Quiche Indians of Guatemala consider *A. muscaria* to be a sacred fungus because, according to Wasson and Wasson (1957), the name "holom-ocox" in the ancient religious pre-conquest book "Popol Vuh" means *A. muscaria*. Interestingly, in both Mexico and Guatemala, *A. muscaria* is now considered to be a "diabolical" mushroom because it is "very poisonous"; at the same time, however, the Indians treat it with respect as a special fungus. In 1977, Villacorta and Villacorta (cited in Torres 1984) postulated that the ancient Maya used sacred mushrooms in their Chichén Itzá sacrifices; in fact, they believed that the victims ate toxic mushrooms before their deaths.

Referring to the Dresden Codex (Dresden Codex Reproduction 1981), Lowy (1980) observed four men (displayed on two pages - two men per page) falling through space, with special leaves on their bodies. Lowy believed that these leaves were stylized mushrooms that related to *A. muscaria*. Other authors believe that those leaves belong to the hallucinogenic plants *Turbina corymbosa* (L.) Raf. (a Convolvulaceae) or *Salvia divinorom* Epl. and Jativa-M. (a Laviatae) (Ott 1993; Schultes and Hofmann 1979; Torres 1984), which are now used as narcotic plants by other Indians in Mexico. Another interpretation of the Dresden Codex "falling men" lies in their relationship with the god of rain (Chak) and the fungus *Ustilago maydis* (DC.) Corda, which will be discussed later in the chapter.

All of the above observations on the use of sacred mushrooms have a connection with the ancient mushroom stones found in the Maya highlands. Wasson and Wasson (1957) and Wasson (1980) presented these mushroom stones as evidence of the ritual involving hallucinogenic mushrooms among the Maya. Sapper, was the first to find a mushroom stone in El Salvador in 1898 (Heim and Wasson 1958; Wasson and Wasson 1957). Sapper's original discovery is now in a museum in Zurich.

Kobayasi, who was very interested in the ethnomycology of Mexico, made several facsimiles of the Sapper mushroom, which he presented in 1983 at the Third International Mycological Congress in Tokyo, Japan. At present, there are more than 300 known pieces of mushroom stone, the majority of them the Maya area in Guatemala, although a few are from other cultures in Mexico (de Borhegyi 1961; Lowy 1971; Mayer 1977).

Guzmán (in Mapes, Guzmán, and Caballero 1981) and Guzmán (1984) reported the existence of a small mushroom stone (34 mm high) from an archaeological site of the Purepecha Culture in Patzcuaro, Michoacán, México, which he identified with a button of *A. muscaria*. The Maya mushroom stones are figures 28 to 38 cm high, with a standing man or animal represented below the cap of a mushroom. Torres (1984) and Ohi and Torres (1994) discussed these figures from Guatemala. Along with the little mushroom stone from the Purepecha region, de Borhegyi (1961) found miniature mushroom stones in Guatemala that are 10 to 19 cm high.

Although standing figures are represented in the above stones, Wasson (1980) and Lowy (1980) mentioned two other interesting figures, where men are falling or plunging into a dreamlike state. These figures show a man with his feet supporting the cap of the mushroom. These falling figures have a strong relationship with the hallucinogenic effects of the sacred mushrooms, because and a person flying in space. According to Lowy (1980), these figures relate to the falling human figures represented in the Dresden Codex, where the falling men are plunging gods - floating or falling from the sky. In fact, anyone who eats hallucinogenic mushrooms feels as if he or she is flying in space; when the effects subside, he or she falls back to earth. According to Wasson (1980) and Lowy (1980), these falling men in the Guatemalan mushroom stones are strong evidence of the ceremonial use of hallucinogenic fungi in the Maya Culture. However, as noted with the Dresden Codex "falling men," another interpretation of these figures (i.e., in relation to Chak, the god of rain, and *Ustilago maydis*) will be discussed later in this paper.

The use of hallucinogenic mushrooms belonging to *Psilocybe* is unknown in the entire Maya region, in spite of the fact that *P. mexicana* Heim, *P. cubensis* (Earle) Singer, *P. subcubensis* Guzmán, and *P. zapotecorum* Heim emend. Guzmán have been reported (Sommerkamp in Ohi and Torres 1994; Torres 1984; Wasson 1980). The first report on a hallucinogenic *Psilocybe* from the Maya region was made by Lowy (1977) in Guatemala. Close to the Yucatán Peninsula in the Tehuantepec Isthmus region (Uxpanapa zone), Guzmán (1979) described the following hallucinogenic species of *Psilocybe*: *P. naematoliformis* Guzmán, *P. singerii* Guzmán, *P. uxpanapensis* Guzmán, and *P. weldenii* Guzmán. It is possible that the use of *A. muscaria* was replaced a long time ago by species of *Psilocybe*, which is what happened in other parts of Mexico. However, at present, there is no evidence of the use of any sacred mushrooms in the Maya area.

Mycological and ethnomycological studies in the Maya area

In spite of the great diversity of fungi not only in the Maya area, but in all the tropical regions, as noted by Guzmán (1998), there are few reports on the fungi of the Maya region. Guzmán (1998) established that although there are more than 200,000 species of fungi in Mexico, we know only about 6,000 of them. As there are more than 70 percent of all fungi in tropical regions, and we only study a few species every year, it would take more than 200 years (at the present pace) to know all the fungi of Mexico. This slow progress is especially disturbing as tropical vegetation is being destroyed at an alarming rate.

The first records of fungi in the Maya area were made by Millspaugh (1896, 1898), who reported relatively few fungi (among them, *Agaricus yucatanensis* Ellis and Everhart) in his study of Yucatán flora. Standley (1930) researched the same area; in his study, Standley presented a checklist of the 22 fungi species recorded from Yucatán. Hedrick (1935) recorded some lichens from Yucatán, while Guzmán (1982, 1983); Guzmán and Johnson (1974); Guzmán and Madrigal (1967); Guzmán-Dávalos and Guzmán (1982); Mata (1987); Pérez-Moreno and Villarreal (1988); Pérez-Silva, Herrera, and Valenzuela (1992); and Ulloa (1974) studied the fungi of the Maya area of Mexico. Of these works, Ulloa (1974) is the only one confined to molds, although Guzmán (1982) described a few micromycetes.

Ulloa (1974) studied the molds that form pozol - a Mayan beverage that was also recorded by de Landa (1560). Guzmán (1982, 1983), and Guzmán-Dávalos and Guzmán (1982), discussed more than 250 species of fungi from 66 localities on the Yucatán Peninsula; some of them were new records, and others were new species. The papers of Guzmán (1983) and Mata (1987) also deal with the ethnomycology of Yucatán. Related to this latter ethnomycological point, Laughlin (1975) presented several Tzotzil names on fungi, while Barrera-Vázquez, Bastarrachea, and Brito-Sansores (1980) considered some few names on fungi in their respective dictionaries of the Maya Region (also transcribed by Guzmán 1997). However, neither Barrera-Vázquez, Bastarrachea, and Brito-Sansores (1980) nor Laughlin (1975) presented any names related with the sacred mushrooms.

Sommerkamp (1991) and Sommerkamp and Guzmán (1990) presented a discussion of the 21 known edible species from the popular markets in Guatemala, and a checklist of the fungi in the Herbarium of the University of San Carlos of Guatemala; Sommerkamp (1994) discussed the known hallucinogenic species of *Psilocybe*. Guzmán, Torres and Logemann (1985) described *Morchella guatemalensis* Guzmán, Torres, and Logemann from Guatemala. Guzmán (1987) discussed *Pseudofistulina radicata* (Schw.) Burdsal from Yucatán, Guatemala, and El Salvador, this latter report being based on Escobar and Toledo (1977). Logemann *et al*. (1987) reported a fatal case of poisoning with *Amanita magnivelaris* Peck in Guatemala. There are at present more than three hundred species of fungi known from the Maya area.

Important species of fungi used at present in Yucatán are *Geastrum saccatum*, *Clathrus crispus*, *Pleurotus djamor*, and *Ustilago maydis*, among others (Guzmán 1983). *Geastrum saccatum* is named "looi lu um" (or "flower of the earth"), and is used to stop diarrhea in children known as "mal de ojo." *Clathrus crispus* is known as "chaaha quai" (i.e., colander of the medicine man or wizard), and is used to control some eye infections using the liquid that is obtained when the mushroom is squeezed. *Pleurotus djamor* is a common pantropical edible fungus known as "xikin che" (or "ear of the woods"); in the present tourist resort of Xcaret (which is close to Cancun, Quintana Roo), employees have a laboratory and greenhouses to cultivate this fungus and cook it in their restaurants. Furthermore, the University of Yucatán, in Merida, has a program on the cultivation of this fungus to teach the technology to the farmers.

There are some important ethnomycological observations to be made regarding *Ustilago maydis*, the edible fungus of the Nahuatl culture known as "huitlacoche", which is a parasitic fungus on corn. This fungus is called "ta chaak," "ta chak ixim," "ixim chaak," and "nal chaak," among other names, all of which are related to Chak, the god of rain. It is believed that this fungus falls on the corn from rain, and that the fungus has concentrated the violence of the thunderbolt (Guzmán 1983; Mata 1987). These interesting observations on the fungus that falls from the sky with all the violence of the thunderbolt are strongly related, and demonstrate the connection of *Ustilago maydis* with the Thunderbolt Legend, the Dresden Codex, and the mushroom stones portraying "falling men," as discussed earlier. Lowy (1974, 1980) stated that the Thunderbolt Legend - which related the thunderbolt with a fungus, and the falling men in both the Dresden Codex and the mushroom stones - are related to the ingestion of *A. muscaria*. Why, then, is all this information not connected with the important edible fungus *Ustilago maydis*, which is also said to fall from the sky? This is a new interpretation, and may be the most proper way of relating "falling men" and the Thunderbolt Legend. As long as different interpretations exist, it is clear how much study is still needed on the Maya Culture in relationship with the fungi.

The project on the fungi of el Edén ecological reserve, Quintana Roo

To cope with the high destruction of vegetation on the Yucatán Peninsula, Arturo Gómez-Pompa (University of California, Riverside) founded a private ecological reserve in the north of Quintana Roo, called "Reserva Ecologica El Edén," to conserve and study the biodiversity of this site. Two explorations took place in 2000 - one in July, and the other in November - to gather all the fungi possible.

More than 400 specimens of fungi, mainly macromycetes, were gathered, as well as some lichens and myxomycetes. A preliminary checklist of studied species was prepared (Table 17.1) noting 65 species, of which *Leucopaxillus gracillimus* is first reported in Mexico. This species was only previously known in Florida, U.S.A., Brazil, and the Antilles (Dennis 1970; Pegler 1983). Moreover, *Fomitopsis rosea*, *Panellus stypticus*, and *Trogia cantharellus* were also first reported on the Yucatán Peninsula.

New species will be described from the material that is now being studied. The ultimate plan is to publish articles and descriptions of any new or interesting species. The main objective of this project is to prepare an illustrated book with color plates of the main fungi of El Edén.

TABLE 17.1. A preliminary checklist of the fungi of El Edén Ecological Reserve

Ascomycotina	*Cookeina sulcipes (Fr.: Fr.) Dennis*
	C. tricholoma (Mont.) Kuntze
	Daldinia eschscholzii (Ehenb.: Fr.) Rehm
	Hypoxylon rubiginosum (Pers.: Fr.) Fr.
	Phillipsia domingensis (Berk.) Berk.
	Phylacia globosa Lév.
	P. poculiformis (Mont.) Mont.
	Xylaria bombooensis Lloyd sesu San Martin & Rogers
	X. cocoophora Mont.
	X. phyllocharis Mont.
	X. polymorpha (Pers.:F.) Grev.
Basidiomycotina	*Agrocybe retigera (Speg.) Singer*
	Auricularia fuscosuccinea (Mont.) Farlow
	A. mesenterica Pers.
	A. polytricha (Mont.) Sacc.
	Clathrus crispus Turpin
	Coprinus radians (Desm.) Fr.
	Coriolopsis byrsina (Mont.) Ryv.
	C. polyzona (Pers.) Ryv.
	Dacryopinax elegans (Berk. & M.A. Curtis) Martin
	Daeladea sprucei Berk.
	Dictyopanus pusillus var. rhipidium (Berk.) Singer
	Earliella scabrosa (Pers.) Gilbn. & Ryv.
	Fomitopsis feel (Fr.) Kreisel.
	Ganoderma curtisii (Berk.) Murrill
	Geastrum campestris Morgan.
	G. saccatum Fr.
	Gloeophyllum striatum (Sw.: Fr.) Murrill
	Hexagonia papyracea Berk.
	H. tenuis Fr.
	Lepista singeri Guzmán
	Leucocoprinus birnbaumii (Corda) Singer
	Leucopaxillus gracillimus Singer & A.H. Smith
	Mycenoporella clypeata (Pat.) R. Heim
	Panaeollus antillarum (Fr.) Dennis
	Panus badius (Berk.) Singer
	P. crinitus (L.: Fr.) Singer
	Phellinus extensus (Lév.) Pat.
	P. gilvus (Schw.: Fr.) Pat.
	P. linteus (Berk. & M.A. Curtis) Teng
	P. pectinatus (Kl.) Quél.
	Phylloporia spathulatha (Hook.) Ryv.
	Pleurotus djamor (Fr.) Boedijn
	P. hygrophanus (Mont.) Dennis
	Pogonomyces hydnoides (Sw.: Fr.) Murrill
	Polyporus tenuiculus (Beauv.) Fr.
	P. tricholoma Mont.
	Pycnoporus sanguineus (L.: Fr.) Murrill
	Rigidoporus microporus (Fr.) Overeem
	Schizophyllum commune Mont.
	S. fasciatum Pat.
	Scleroderma sinnamariense Mont.
	Trametes maxima (Mont.) David & Rajch.
	T. villosa (Fr.) Kreisel
	Trichaptum perottettii (Lév.) Ryv.
	Tremella rubromaculata Lowy.
	Trogia cantharellus (Mont.) Pat.
	Volvariella volvacea (Bull. : Fr.) Singer

Lichens	*Coenogonium linkii Ehrenb.* *Graphis librata (L.) Anch.* *Strigula complanata Mont.*
Myxomycota (Myxomycetes)	*Arcyria denudata (L.) Wettst.* *Ceratiomyxa fruticulosa (Müll.) Macbr.* *Stemonites splendens Rostafineski*

original report: http://citeseerx.ist.psu.edu/viewdoc/download?doi=10.1.1.372.1415&rep=rep1&type=pdf

Table of Contents:

Introduction
1. Psychedelic/Neurochemical Models of Paranormal Experience
  1.1 Brain as filter
  1.2 β-carbolines, tryptamines, and psi
  1.3 DMT, near-death, and other anomalous experiences
  1.4 Ketamine and NDEs
  1.5 Dopamine and paranormal beliefs and experiences
  1.6 Overview of psychedelic/neuro-chemical models of paranormal experience
2. Field Reports of Paranormal Phenomena
  2.1 Anthropological and Historical Reports
  2.2 Personal Views and Experiences
  2.3 Clinical
  2.4 Evaluation of Field Reports
3. Surveys
  3.1 Surveys of Belief in the Paranormal
  3.2 Surveys of Paranormal Experiences
    3.2.1 Psychiatric epidemiological samples
    3.2.2 Clinical populations
    3.2.3 General and student samples
    3.2.4 Psychedelic-users samples
  3.3 Surveys and Out-of-Body Experiences (OBEs)
  3.4 Summary of Survey Research
4. Experimental ESP Research
  4.1 Forced-Choice Designs
  4.2 Free Response
    4.2.1 Psychometry (object reading)
    4.2.2 Other clairvoyance experiments
    4.2.3 Telepathy experiments
  4.3 Summary of Experimental Research
5. Methodological Critique of Experimental Research
6. General Summary and Conclusions
Acknowledgements
References

David Luke

This paper investigates the relationship between psychoactive substances and so-called paranormal phenomena falling within the study of parapsychology. It is primarily concerned with extrasensory perception (ESP) - telepathy, precognition, and clairvoyance - as well as out-of-body experiences (OBEs) and near-death experiences (NDEs). Psychokinesis (PK), aura vision, encounter experiences, and sleep paralysis only make a very limited contribution to this review as they are seldom related to psychoactive drugs within the parapsychological literature. The paper borrows widely, but by no means exhaustively, from parapsychology as well as transpersonal studies, anthropology, ethnobotany, phytochemistry, psychiatry, psychotherapy, psychopharmacology, and neurobiology, particularly neurochemistry. It is organized into neurochemical models of paranormal experience (section 1), field reports of intentional and spontaneous phenomena incorporating anthropological, historical and clinical cases, and personal accounts (section 2), surveys of paranormal belief and experience (section 3), experimental research (section 4), and a methodological critique of the experimental research with recommendations for further work (section 5).

Keywords: psychedelic, hallucinogen, entheogen, neurochemistry, parapsychology, psi, ESP, clairvoyance, telepathy, precognition, OBE, NDE.

Introduction

Ever since the beginning of the 20th century when Western scientists and academics began earnestly turning their attention to psychedelics there has been a clear association between the use of these substances and the transpersonal or paranormal experience. Indeed, those people most readily associated with the discovery and popularization of psychedelics also witnessed and explored both the transpersonal and the parapsychological dimensions that these substances induced, such as Albert Hofmann, Humphrey Osmond, John Smythies, Aldous Huxley, Gordon Wasson, Timothy Leary, Ken Kesey, Duncan Blewett, Walter Pahnke, James Fadiman, and Stanislav Grof, to name but a few (Luke, 2006; Stevens, 1988). The overlap between transpersonal and paranormal experiences is apparent (e.g., Daniels, 2005), but while a great deal has been written in recent years about psychedelic experiences from the transpersonal perspective, a comprehensive review of the parapsychological literature relating to psychedelic experiences is long overdue.

This review focuses primarily on the class of psychoactive substances that largely induce visionary and trance-like experiences. For the purposes of the present review this includes drugs and sacramentals such as mescaline, lysergic acid diethylamide (LSD), psilocybin, ayahuasca, *N,N*-dimethyltryptamine (DMT), marijuana (which is treated as a psychedelic in the current review), and ketamine, but not opiates or cocaine. This class of visionary substances has been termed differently by different authors, usually dependent upon the connotation they wish to convey about the psychoactive effects or how the substance is used. Within the literature of the present review, they have been termed "mind-expanding" (e.g., Palmer, 1979), "psychotropic" (e.g., Irwin, 1994), "psychodysleptic" (Cavanna & Servadio, 1964), "hallucinogenic" (e.g., Blackmore, 1992), and even "entheogenic" (Ruck, Bigwood, Staples, Wasson, & Ott , 1979), meaning bringing forth the divine within, which is a useful term to convey the apparent divinatory and visionary nature of these substances (for discussions see Letcher, 2004; Ott, 1996; Smith, 2000), although they might be more correctly termed "potential entheogens" as they do not automatically produce such experiences (Krippner, 2006b, p. 1). Finally, there is the most frequently used term, "psychedelic", which was created in 1956 by Humphry Osmond and means "mind manifesting" (Osmond, 1961a, p. 76). Where specified, the original term used by the authors will be preserved to reflect their orientation to the issue. However, elsewhere, where appropriate, the more widely used term "psychedelic" will be used.

For the purpose of the present paper, a psychedelic drug is:

> one which, without causing physical addiction, craving, major physiological disturbances, delirium, disorientation, or amnesia, more or less reliably produces thought, mood, and perceptual changes otherwise rarely experienced except in dreams, contemplative and religious exaltation, flashes of vivid involuntary memory, and acute psychoses. (Grinspoon & Bakalar, 1998, p. 9)

The earliest parapsychology experiments with psychoactive substances were conducted with simple stimulants and depressants, such as caffeine, amphetamine, alcohol, amytal, and quinal-barbitone (e.g., Averill & Rhine, 1945; Cadoret, 1953; Huby & Wilson, 1961; Murphy, 1961; Rhine, 1934; Rhine, Humphrey, & Averill 1945; Soal & Bateman, 1954; Wilson, 1961, 1962; Woodruff, 1943). This work is not included here (for reviews see Palmer, 1978; Ramakrishna Rao, 1966) as this review is instead focused on the visionary substances, which are seemingly more favorable to the production of psi, that Braud (2002) has suggested primarily cause qualitative, rather than just quantitative alterations to the user's state of consciousness, although Rock and Krippner (e.g., 2012) argued that (altered) states of consciousness may be more accurately described as (altered) states of phenomenology. Some earlier reviews of psychedelics in parapsychology are available and have been incorporated into the present investigation (Blewett, 1963; Gowan, 1975; Krippner & Davidson, 1970, 1974; Luke, 2008b; Luke & Friedman, 2010; Parker, 1975; Rogo, 1976; Wilson, 1949).

There are good theoretical reasons for investigating psychedelics as a means of inducing ESP and other paranormal phenomena. Given that an altered state of consciousness (ASC) is assumed to be (for a discussion see Storm & Rock, 2009) a common feature in the occurrence of subjective paranormal experiences (Alvarado, 1998; Barušs, 2003; Honorton, 1977; Parker, 1975) and has often been incorporated into experimental attempts to induce ESP (see Luke, 2011a; Palmer, 1978, 1982; Schmeidler, 1994), then visionary drugs are, potentially, a reliable means of accessing such a state. Several researchers have documented some of the mind-altering features of the visionary-drug experience that are considered conducive to the production of parapsychological experiences and phenomena (see also Braud, 2002). These have been categorized thus:

1. Increase in mental imagery, in both vividness and quality, and the dreamlike state (Blackmore, 1992; Osis, 1961a, 1961b; Progoff, 1961; Tart, 1968, 1994)
2. Altered perception of self-identity, such as unity consciousness: The mystical experience of becoming one with everything in the universe (Krippner & Fersh, 1970; Nicol & Nicol, 1961; Osis, 1961a; Pahnke, 1968; Tart, 1994)
3. Altered body perceptions and dissociation (Blackmore, 1992; Tart, 1994). This is of particular interest with respect to the out-of-body experience (OBE)
4. Distorted sensory input (Blackmore, 1992)
5. Increased absorption and focused attention (Millay, 2001; Tart, 1968, 1994)
6. Increased empathy (Blewett, 1963; Nicol & Nicol, 1961; Tart, 1994). This is of interest to telepathy, and indeed, elevated empathy is associated with use of psychedelics generally (DeGracia, 1995; Lerner & Lyvers, 2006)
7. Emotional flexibility (Blewett, 1963), which may also assist in negotiating the fear of psi (Tart, 1994)
8. Increased alertness and awareness (Huxley, 1961a; Nicol & Nicol, 1961; Osis, 1961b; Tart, 1994)
9. Increased inwardly focused attention and awareness, and decreased external and bodily awareness (Dobkin de Rios, 1978)
10. Increased spontaneity (Osis, 1961a)
11. Sensitivity to subtle changes (Parker, 1975) and intensity of feeling (Osis, 1961a)
12. Physical relaxation (Blackmore, 1992), although Tart (1968) questions its occurrence
13. Increased suggestibility (Huxley, 1961a; Tart, 1968)
14. Increase in intuitive thought processes (Tart, 1994)
15. Reduced critical conscious faculty and increased optimism towards impossible realities (Nicol & Nicol,

1961; Osis, 1961b; Tart, 1968, 1994)

16. Increased openness and extroversion (Rogo, 1976)
17. Release of repressed and unconscious material into the conscious mind (Rogo, 1976)
18. Complex distortions, and transcendence, of space and time (Garrett 1961b; Nicol & Nicol, 1961; Tart, 1994; see also Dawson, 2005; Mayhew, 1956; Shanon, 2001; Whiteman, 1995)

This last feature of the psychedelic experience is probably of paramount importance for the experience of ESP when it is considered that precognition, telepathy, clairvoyance, and possibly OBEs all represent radical departures from Newtonian concepts of time and space. Smythies (1983) has suggested that the psychedelic experience originates from the collective unconscious outside of space and time, and Jung agreed with Smythies' idea. Millay (2001) offered that psilocybin and similar substances are important for studying psi because they allow us access to nonlocal space-time. Jansen (1999) also supposed that the same might be possible of ketamine, which became popularly used at the same time as Bell's theorem of nonlocal space-time was becoming seriously considered, enabling some to report the experiential equivalence of the concept. Indeed, the Berkley-based Fundamental Fysiks Group that formed in the 1970s experimented with psychedelics to inspire their investigations of both psi and Bell's theorem - neglected as it was by mainstream physics at that time - which eventually lead to the birth of what is now the multi-billion dollar research enterprise of quantum information science (Kaiser, 2011). More recently, something akin to this may also be evident with the psychedelic substance DMT, which sometimes provides users with the perception of many more than the usual four space-time dimensions, perhaps comparable to what physicists discuss in M-theory (Luke, 2010c). Keeping with the times ketamine is also now reported to induce such extra-dimensional percepts too (Newcombe, 2008), as is the semi-synthetic psychedelic salvinorin B ethoxymethyl ether (Mercury & Feelodd, 2008).

In addition to these temporary alterations that occur during the psychedelic experience, it is arguable that long-term ideological alterations may occur that might also be psi-conducive. For example, enduring changes in concepts of reality may occur with the use of psychedelics (Conway, 1989; Strassman, 2001), such that optimism about unseen realities, both during and after the experience, leads to a greater openness to, or belief in, psi and the paranormal. In a follow-up survey of 113 LSD-psychotherapy clients (with an 82% response rate) 78% reported an increased tendency to view telepathy and precognition as possibilities warranting investigation (International Foundation for Advanced Study, 1962). It has even been stated that the psychedelic experience is itself, by common consent, paranormal (Unger, 1963). Furthermore, the distinguished medium and psychical researcher Eileen Garrett (1961b) asserted that the use of LSD had made her a better, more accurate sensitive and she related certain psychedelic states to the mediumistic pre-trance state of euphoria, although she specified that the LSD experience was not the same as the mediumistic trance (Garrett, 1961a). Huxley (1961a) proposed that LSD is invaluable in training participants to use their subjective faculties to enhance their psi ability.

Besides the subjective aspects of the psychedelic experience, there are other theoretical reasons for investigating paranormal phenomena with drugs: Because paranormal phenomena are brain-mind experiences, neurochemicals - and therefore psychoactive drugs - would be expected to be involved in the process. It is highly likely that all ASC, including potentially ESP-conducive states, involve alterations in brain chemistry. Indeed, several psychedelic-neurochemical models, discussed in the following sections (also see Luke & Friedman, 2010), have been proposed, primarily based upon subjective paranormal experiences occurring with certain substances and their specific neurochemical action. It is entirely feasible that genuine paranormal experiences are mediated in the brain through the action of specific endogenous (made within the body) molecules (Vayne, 2001). This does not simply imply that neurochemicals are the sole cause of paranormal phenomena, but they may rather just be a part of the process. As the novelist Aldous Huxley once said in relation to mystical experiences and the use of psychedelics - they are the occasion rather than the cause.

1. Psychedelic/Neurochemical Models of Paranormal Experience

1.1 Brain as filter

Aldous Huxley (1954) also was prominent in promoting Henri Bergson's (1896/1990) theory of the brain as a filter of memory and sensory experience, acting to reduce the wealth of information available to awareness lest people become overwhelmed by a mass of largely useless and irrelevant data not needed for the survival of the organism. It was Bergson who suggested that, if these filters were bypassed, humans would be capable of remembering everything that had ever been experienced and perceiving everything that has happened everywhere in the universe (e.g., as in clairvoyance). It was also Huxley who applied this theory to psychedelics by suggesting that these mind-manifesting drugs override the "reducing valve" of the brain (Huxley, 1954, p. 12), allowing humans access to both psychic and mystical experiences. This was a notion that Huxley eruditely paraphrased for the title of his book from the quote by the English poet and mystic, William Blake (1906/1793), "If the doors of perception were cleansed, every thing would appear to man as it is, infinite" (p. 26).

Huxley's (1954) rather basic conception never received a more formal operationalization of the specific drug actions that may be involved, but research into the neurochemistry of psychedelics lends some support to his notion. For instance, Vollenweider and Geyer (2001) proposed that information processing in cortico-striatothalamo-cortical (CSTC) feedback loops is disrupted by psychedelics via 5-HT (serotonin) receptor agonism (specifically 5-HT$_{2A}$ receptors), thereby inhibiting the "gating" of extraneous sensory stimuli and inhibiting the ability to attend selectively to salient environmental features. Furthermore, psychedelics are also thought to induce presynaptic release of glutamate from thalamic afferents, leading to a simultaneous overload of internal information in the cortex. It is thought that these combined information overload effects are at least partly responsible for the hallucinogenic experience with these drugs, which are known to induce greatly altered or amplified incoming sensory information, as is indicated by an increased startle effect (Vollenweider, 2001).

Research into the neurobiology of psychedelics in humans has only just resumed after decades of dormancy, so the current understanding of the action of these substances in the brain remains limited. One of the few studies to have been conducted, however, also offers some unexpected support for Huxley's reducing valve theory. Looking at the blood flow around the brain following the ingestion of psilocybin, it was expected that certain regions of the brain would have more activity, given the overwhelming intenseness of strong psychedelic experiences, and yet, counter-intuitively, there was no single brain region that increased in activity, and the brain's activity was reduced overall (Carhart-Harris, 2011; Carhart-Harris *et al*., 2012). The main areas demonstrating reduced cerebral blood flow were the cerebral hub regions of the thalamus, anterior and posterior cingulate cortex (ACC & PCC), and medial prefrontal cortex (mPFC). Significantly, the usual positive coupling between the mPFC and the PCC - which forms part of the default mode network thought to be important in introspection and high level constructs such as self and ego - was reduced leading to "a state of unconstrained cognition" (Carhart-Harris *et al*., 2012, p. 2138).

This psychedelic disruption of the sensory gating function discussed by Vollenweider (2001), and the reduction of activity in the default mode network discussed by Carhart-Harris (2011) could also underpin the neurochemistry of ESP, whether elicited with any number of psychedelics or, indeed, without the intervention of such exogenous chemicals (though perhaps via endogenous chemicals such as DMT). Indeed like psychedelics, psi experiences and events have variously been conceptualized in relation to an inhibition of the ordinary sensory inhibition, often in conjunction with elevated psychosis and creativity, such as with the concepts of latent disinhibition (Holt, Simmonds-Moore, & Moore 2008), transliminality (Thalbourne, 2000; Thalbourne & Houran, 2005), boundary thinness and schizotypy (Simmonds & Roe, 2000), and self-expansiveness (Friedman, 1983; Pappas & Friedman, 2007). It may be noted that psychedelics have also been long associated with both creativity (e.g., Dobkin de Rios & Janiger, 2003; Krippner, 1985) and psychosis (Osmond & Smythies, 1952).

Despite the simplistic appeal of the anti-reducing valve action of psychedelics as a neurochemical model of psi, considerable gaps still remain in the current understanding of the neuropharmacological action of psychedelics in humans. Since the early 1970s, until relatively recently, practically all psychedelic research has been conducted with animals and there remain no definitive generalizations that can be made about the main neurotransmitter receptor sites involved, as psychedelics vary considerably in their chemical makeup and their ligand (i.e., a ligand is a molecule, such as a neurotransmitter, that triggers a response in a target protein) affinity (Ray, 2010). For instance, dissociative anesthetics such as ketamine are commonly N-methyl-D-aspartate (NMDA) receptor antagonists, whereas the simple tryptamines, such as psilocybin, are apparently 5-HT_{2A} agonists. Speculations about the cause of the hallucinogenic effects of psychedelics generally include the activation of 5-HT_{1A}, 5-HT_{2A}, 5-HT_{2C}, dopamine, and glutamate pathways, although it is generally believed that classic psychedelics primarily work by stimulating 5-HT_{2A} receptors, particularly those expressed in the neocortical pyramidal cells (Lee & Roth, 2012; Nichols, 2004), although this is certainly not the case for all psychedelics (e.g., mescaline; Ray, 2010). Electrophysiology and receptor studies have revealed that both NMDA antagonists (e.g., ketamine) and classic serotonergic psychedelics (e.g., LSD) may actually enhance glutamatergic transmission via non-NMDA receptors in the frontal cortex. This may indicate a common mode of chemical action in the brain responsible for such similar experiences with these divergent molecules (Vollenweider, 2004); this serotonin/glutamate receptor-complex model of drug action is receiving high-profile attention again for psychedelics as a possible comparative model of psychosis (e.g., González-Maeso *et al.*, 2008).

Despite the lack of understanding of the neurobiology of psychedelic action, and lack of generalizability across so many diverse substances, recent advances would appear to support the Bergson-Huxley notion of brain as a filter capable of being deactivated by chemicals, and furthermore this notion, including the parts pertaining to ESP, is now gaining ground once more among theorists of consciousness (e.g., Kastrup, 2012). Indeed, recent theoretical developments (Smythies, 2011) suggest that NMDA antagonism, such as via ketamine, bypasses the reducing valve/filter action of the brain (see section 1.4 following below for a discussion).

1.2 β-carbolines, tryptamines, and psi

Advancing on earlier suggestions about the pineal gland's involvement in psi (e.g. Miller, 1978; Sinel, 1927), Roney-Dougal (1986, 1989, 1991, 2001) has developed an endogenous neurochemical-perspective of psi based on the action of the pineal and several hallucinogenic substances found in ayahuasca, the visionary Amazonian brew reported to induce a range of paranormal experiences. The common neurotransmitter serotonin is known to be most active in the pineal gland, where it follows a circadian rhythm and is converted at night into melatonin (5-methoxy tryptamine, or 5MT) and the β-carboline, pinoline (6-methoxy tetrahydro-β-carboline, or 6-MeO-THβC), which regulate sleep cycles. The pineal may also create other β-carbolines, such as 6-methoxyharmalan, a harmala alkaloid. These β-carbolines block the neuronal uptake of serotonin making it available for use, and inhibit the enzyme monoamine oxydase (MAO), which breaks down certain tryptamines such as *N,N*-dimethyl-tryptamine (*N,N*DMT, or simply DMT) and 5-methoxy tryptamine (5-MeO-DMT). MAO inhibitors, such as pinoline or the harmala alkaloids, make serotonin available at the pineal where, with the aid of pineal enzymes (methyl transferases), it can also be converted into 5-MeO-DMT, DMT, and bufotenine (5-hydroxy*N,N*-dimethyl-tryptamine, 5-HO-DMT), which are endogenous visionary substances also found in certain ingredients (such as *Psychotria viridis*) of ayahuasca brews and other shamanic visionary substances, even some of animal origin (e.g., the Sonoran desert toad, Rudgley, 2000). *In vivo* biosynthesis of DMT might also occur through the conversion of the common, nutritionally essential, amino acid tryptophan (Jacob & Presti, 2005; Shulgin & Shulgin, 1997).

However, these endogenous visionary tryptamines are not orally active, as they are denatured by the MAO enzymes present in the stomach, but ayahuasca brews also contains plant additives (such as *Banisteriopsis caapi*) containing a range of harmala alkaloids that inhibit MAO and allow the complementarily ingested visionary tryptamines to be active in the brain. It is this action of the β-carbolines (particularly harmine) in ayahuasca that is these days considered their primary purpose as admixtures in the brew (e.g., McKenna, 2004), though this may not always be the case as subjectively potent ayahuasca decoctions occasionally do not actually contain DMT when analyzed (Callaway, 2005). Nevertheless the harmala alkaloids are also known to induce visions themselves and Roney-Dougal (1986, 1989, 1991, 2001) originally implicated β-carbolines, such as the endogenous pinoline and the exogenous harmala alkaloids, as inducing psi-conducive states, either naturally during dreams (Callaway, 1988) or artificially by causing waking dream states. Roney-Dougal (2001) also later acknowledged that the β-carbolines may exert their visionary effects by potentiating the effects of ingested visionary tryptamines like DMT or 5-MeODMT when consumed in combination with them, as in ayahuasca. Further to Roney-Dougal's proposals, it is my speculation that the β-carbolines may also induce visions by contributing to the endogenous manufacture of visionary tryptamine substances, either when taken alone or in combination with such tryptamines, perhaps even indicating endogenous DMT or related tryptamines as the primary or even sole cause of such visions. This may account for why harmala alkaloids are less effective and slower than DMT at inducing visions (see Shulgin & Shulgin, 1997). In essence, ayahuasca contains two types of visionary chemicals, one type (β-carbolines, e.g., harmine) that helps to both create and potentiate the effects of the other type (tryptamines, e.g., DMT), potentially mimicking the nocturnal chemistry of the pineal and its supposed control over natural visionary states, such as dreams (Callaway, 1988), mystical experiences, and NDEs (Strassman, 2001).

Roney-Dougal (1989, 1991, 2001) suggested that the pineal gland and its neurochemistry is important in the occurrence of psi phenomena and points to the association made by yogis between the pineal gland and the ajna chakra, the yogic psychic center that controls psi-experiences in those with awakened kundalini (Miller, 1978; Satyananda, 1972). Further to this, Naranjo (1987) noted that both kundalini and ayahuasca experiences, being similar in many respects, also feature the same serpentine imagery, further speculating that they probably have the same neurochemistry and result in the same bioenergetic activation.

There is also some possibility that pineal gland activity or DMT production can be stimulated by certain esoteric yogic practices, such as kechari, which involves pressing the tongue into the far rear roof of the mouth to stimulate the production of amrit, a yogic nectar that reputedly causes DMT-like ecstasies, which is supposedly secreted in the brain following prolonged practice (Motoyama, 2001; Satyananda, 1996). Some support for this speculation comes from Strassman's (2001) observation that the pineal gland is formed in utero from the tissue of the roof of the mouth rather than in the brain, and later migrates to its unique ventricle position just outside the blood-brain barrier, directly above a critical cerebrospinal fluid byway, and this tentatively suggests that pineal stimulation via the roof of the mouth may be possible. Furthermore, manifestation of very specific body vibrations said to be classic kundalini symptoms are supposedly quite reliably induced with substances such as DPT (*N,N*-dipropyltryptamine) and 4-Acetoxy-DIPT (*N,N*-diisopropyl-4-acetoxy-tryptamine), which are even more obscure psychedelic tryptamines than DMT, but close relatives of it (Toad, 1999a, 1999b). Similarly, Grof (2001) has reported spontaneous kundalini arousal occurring during psychedelic psychotherapy sessions and surveys (see section 3.2.3 & 3.2.4 to follow) of kundalini experiences have found them to be related to drug use (DeGracia, 1995; Thalbourne, 2001).

Roney-Dougal (1989, 1991, 2001) also indicated that the pineal gland is sensitive to - possibly changing its chemical production - the same fluctuations in geomagnetic activity that appear to be associated with spontaneous psi-activity, possibly related to pineal melatonin (Persinger, 1988) or DMT fluctuations (Hill & Persinger, 2003) - for a review see Roney-Dougal, Ryan, and Luke (2012). That the pineal gland is central to psi is further supported by anthropological research, to follow - although experimental evidence is lacking - that suggests that DMT and the harmala alkaloids found in ayahuasca are psi-conducive, along with clinical research that suggests that pinoline and melatonin regulate sleep cycles and dreaming, during which spontaneous psi experiences most often occur (Roney-Dougal, 1986, 1989, 1991, 2001). Durwin (2001) has further suggested that the total isolation in the dark undergone for either the first 9 or 18 childhood years of the lives of trainee shamans of the Andean Kogi causes pineal gland deformation (presumably by melatonin/pinoline overproduction) that is responsible for their renowned divinatory skills.

Some tentative support for the notion that ESP performance is directly predicted by pineal gland activity is also evident with experimental research that demonstrated prepubescent children score better on ESP tests at 3 a.m., when the pineal's nocturnal chemicals (melatonin, etc.) are supposedly at peak concentrations in the brain, rather than at 9 p.m. (Satyanarayana, Rao, & Vijaylakshmi, 1993). This effect was not evident with a comparable group of pubescent children, which the authors suggest might be expected because the pineal is less active after infancy. A more extensive follow-up investigated dream-ESP and circadian pineal rhythms among young adults finding a significant improvement in dream precognition scores at 3 a.m. compared to 8 a.m. (Luke, Zychowicz, Richterova, Tjurina, & Polonnikova, 2010, 2012) with scores in the same direction but nonsignificant in a replication study (Luke & Zychowicz, 2011), providing some tentative support for the notion that ESP may be linked to circadian pineal rhythms.

Roney-Dougal (2001) has also drawn parallels between the ostensibly psi-conducive nature of the shamanic trance state, psychotic states, psychedelic states, and the dream state, which she suggested all belong to the same continuum - perhaps somewhat akin to Thalbourne's (1998) concept of transliminality, the proclivity for psychological material to cross thresholds in or out of consciousness - and that they all show suggestive evidence of being regulated by the same neurochemical processes. Recently, the discovery of trace amine receptors in the brain for which DMT shows greater affinity than does serotonin - its more common neuroamine cousin - has lead to a resurgence of interest in endogenous DMT in the mediation of mental health (Jacob & Presti, 2005).

1.3 DMT, near-death, and other anomalous experiences

After extensive research investigating the phenomenological effects of administering intravenous injections of DMT, Strassman (2001) has independently hypothesized a role for DMT similar to that suggested by Roney-Dougal (2001). Strassman echoed the same neurochemical action of the pineal as Roney-Dougal, and similarly proffered that psychotic, dream, meditation, and mystical states all occur through the overproduction of DMT, implicating DMT as a "reality thermostat" (Strassman, 2001, p. 327). However, Strassman indicated the action of DMT, not β-carbolines, as primary in producing these states and alternatively proposed that the pineal gland and endogenous DMT are central during extraordinary events, such as birth, death, and the near-death experience (NDE).

To support this view Strassman noted that the anatomy of the pineal, suspended in cerebrospinal fluid outside of the blood-bathed brain, is independent enough to resist activation by normal stresses and yet is optimally situated to deliver DMT directly to the middle brain regions where DMT-sensitive serotonin receptors are involved in mood, perception, and thought. Furthermore, access to the brain in this way eliminates the need for DMT transportation in the blood - where it would be broken down by MAO enzymes anyway - thereby negating the need for a pumping heart for delivery. Jacob and Presti (2005) also noted that DMT is virtually unique among endogenous neurotransmitters in that it is a molecule small enough to have blood-brain barrier permeability. That melatonin exerts its influence slowly over a period of a day or more, and so does not need the pineal's unique location, further supports the supposed postmortem function of DMT. Strassman further speculated that the pineal might continue to produce postmortem DMT for a few hours. He also noted that the NDE has psychedelic and mystical qualities, and that the DMT experience often shares the same features as an NDE. Some of his DMT study participants reported NDEs and death-rebirth experiences, with many others reporting a newfound fearlessness of death. However, that the participants may have been inadvertently primed for these experiences cannot be ruled out because they were told in the briefing to expect feelings of death or impending death. Nonetheless, independent survey research indicates that DMT users sometimes do report death-like and near-death-type experiences (Luke & Kittenis, 2005).

To Strassman's (2001) surprise many of the participants in his DMT study reported contact with sentient beings during the experience, often described as elves, dwarves, imps, gremlins, clowns, reptilian beings, and aliens, but also as spirits, gods, or just as a presence, which was commonly supremely powerful, wise, and loving. Such prevalent encounter experiences with DMT use (for a review see Luke, 2011b) are seemingly so unique and reliable (e.g., Meyer, 1993) as to have had the impish characters popularly dubbed the "self-transforming machine elves" (McKenna, 1991, p. 16), and whose tangible reality has been hotly debated by other DMT-experience researchers (Carpenter, 2006; Kent, 2005, 2010; Luke, in press; Pickover, 2005). Strassman suggested that fluctuations in endogenous DMT levels were also responsible for the frequent reports elsewhere of alien abduction, which share the newfound fearlessness of death and visions of energy tunnels, or cylinders of light, in common with DMT experiences. Following personal experiences with ayahuasca, Severi (2003) likewise noted the similarity between NDEs, traditional psychedelic-induced shamanic initiations, alien abduction experiences, and heightened psychic sensitivity, as have previous researchers (e.g., Harvey-Wilson, 2001; McKenna, 1991; Ring, 1989, 1992). However, Barušs (2003) pointed out that, despite the similarities, DMT and alien abduction experiences lack specific similarities, such as the absence with DMT of the classic "grays" (small gray aliens). Nevertheless, Hancock (2005), also having experienced DMT and ayahuasca, argued that there are substantial similarities between aliens and elves, whether induced through DMT or else appearing in historic-folkloric legends and testimonies, speculating that the latter also have a DMT-induced etiology and, adopting the theory proposed by Vallee (1969), that these elves of folklore are the prototype encounter/abduction experiences. It should be noted that few experiencers ever doubt the reality of their encounters with either aliens (Mack, 1999) or DMT entities (Strassman, 2001), perhaps with the exception of Kent (2005, although see Kent, 2010) in this latter category, and most actually consider them to be more real than most ordinary experiences. Additionally, like alien abduction reports, Strassman notes that his DMT study participants reported being probed and having things inserted into them by the beings, however, it should be noted that this might have been induced by the medical nature of his experiments and the use of intravenous injections and equipment for monitoring vital signs.

Incidentally, although neither Strassman nor other researchers originally pointed this out, it is apparent that some of the DMT experiences reported in his study, particularly the negative ones, share several features in common with sleep paralysis (e.g., see Cheyne, 2001), particularly the sense of presence, reports of one's chest being crushed, strange whistling, whining, and whirring sounds, and the terrifying paralysis of both body and vocal chords (Strassman, 2001). Alien abduction experiences and NDEs are also associated with sleep paralysis (see Sherwood, 2002), and indeed Strassman (2008) later noted the apparent relationship between sleep paralysis and DMT experiences, although caution has been raised about claiming too many anomalous phenomena can be explained by DMT, as this ultimately explains nothing, and further phenomenological analysis is needed (Luke, 2008), such as that conducted by Cott & Rock (2008), although a direct comparison of such experiences is needed. Nevertheless, there certainly warrants something to research here regarding a DMT etiology for sleep paralysis.

Curiously, experiential reports from research programs in the 1950s and 1960s (outlined in Shulgin & Shulgin, 1997; Torres & Repke, 2006), indicate that the endogenous 5-hydroxy-DMT (bufotenine), a very close relative to DMT with similar neurochemistry, is seemingly able on occasion to cause feelings of constriction in the throat and the crushing of one's chest, as well as anxiety and fear reactions, much like sleep paralysis, possibly implicating it as a co-chemical factor in such experiences, along with DMT. Additionally, in South America and the Caribbean the entheogenic cohoba snuff is made from one of the few traditionally-used plants in which bufotenine is active, *Piptadenia peregrina*, and is used specifically to contact spirits (Cohen, 1970; Torres & Repke, 2006), perhaps somewhat like the sensed presences of sleep paralysis and numerous DMT experiences. However, Ott (2001) pointed out that the circulatory crises in the earlier bufotenine research were most likely due to psychological factors caused by the enforced nature of the experiments - conducted as they were on psychiatric patients and prisoners with limited consent - because such experiences were absent during Ott's own extensive self-experimentation, and nor do indigenous users of plants containing bufotenine worry about or report respiratory arrest (Torres & Repke, 2006). In any case the breathing difficulties associated with sleep paralysis may be more to do with the paralysis of conscious bodily functions caused by being asleep, and the inability to inhale at will. Furthermore, sensed presence, as opposed to direct perception of an entity, as often occurs with sleep paralysis, may be more common with other substances, such as *Salvia divinorum* (Aardvark, 2002; Addy, 2010; Arthur, 2010) (meaning something like "diviner's sage"), although systematic phenomenological research is needed.

In evaluation of the role of the pineal gland and endogenous psychedelics in the activation of psi and the NDE, it has yet to be shown that psi can be produced with these substances under controlled conditions. In addition, both psi experiences and NDEs might be induced with other psychoactive substances, as shown in the following sections, although this criticism has been countered by Strassman (2001) with the possibility that other psychedelic substances may also stimulate the pineal and endogenous DMT by their action. However, this proposal is little more than conjecture. Furthermore, although there is good reasoning for the hypothesis that DMT is made in the human pineal, this is yet to be proven and remains speculative, like many of Strassman's and Roney-Dougal's suppositions at the present time.

According to Strassman (2001), although the lungs, liver, blood, and eye all contain the enzymes necessary to convert tryptamine to DMT, the pineal gland is especially rich in them and also has high concentrations of serotonin ready to convert to tryptamine. So while the pineal-DMT hypothesis is currently unproven (Hanna, 2010), it is certainly feasible, especially when it is considered that the chemical conversion of tryptamine to DMT can be demonstrated en vitro. The only attempt thus far to support the hypothesis directly has been Strassman's attempt to isolate DMT from 10 human pineal glands extracted from cadavers. No DMT was detected in the glands; however, neither the bodies nor the glands were freshly frozen and any chemicals present may have degraded before analysis (Strassman, 2001).

Thus far DMT has been found to be naturally occurring in the brains of rodents (Kärkkäinen *et al.*, 2005), and in the highest concentrations in humans in the cerebrospinal fluid (for a review, see Barker, McIlhenny, & Strassman, 2012), but not the brain, let alone the pineal. Furthermore, although the pineal contains methyltransferase enzymes, as Strassman (2001) indicated, the particular one thought to be crucial for *en vivo* DMT production (indolethylamine N-methyltransferase, or simply INMT) has as yet not been found in the human brain or pineal gland although, curiously, DMT was found in rabbit brain tissue, despite the absence of INMT (Kärkkäinen *et al.*, 2005), perhaps indicating that INMT is not necessary for the production of DMT. Furthermore, McIlhenny (2012) pointed out that most INMT mapping research only establishes where enzyme translation is occurring, as they are based solely on INMT mRNA studies. A recent study (Cozzi, Mavlyutov, Thompson, & Ruoho, 2011) using a fluorescent INMT antibody suggests the presence of INMT in three *Rhesus macaque* nervous tissues samples, including the pineal gland. Evidence of INMT in primate pineal glands indicates better potential for Strassman's human pineal-DMT production hypothesis, nevertheless direct support is still lacking. However, absence of evidence is not evidence of absence, and the pineal gland is difficult to research *en vivo* and DMT is an under-researched substance, particularly in humans. DMT is also difficult to detect (Barker *et al.*, 2012) and belongs to the most controlled category of drugs in most countries, so, currently, the jury remains out on the pineal-DMT hypothesis.

Overall, despite their incompleteness, the pineal/β-carboline/DMT models of psi and NDE do offer unique neurochemical perspectives on paranormal experience around which further research can be framed. Additionally, although neither author has speculated on the others' ideas, their models are not incompatible with each other; however, they may begin to answer the question of why such visionary molecules as DMT are made within humans at all. For a further discussion of DMT, brain action and anomalous phenomena, see Luke (2011b).

1.4 Ketamine and NDEs

A proliferation of reported cases of NDEs with the use of ketamine (Jansen, 1997a, 1999, 2001) and the similarity of aspects of the ketamine experience to that of the NDE (Morse, Venecia, & Milstein, 1989; Rogo, 1984) - despite Morse's (1997) later contentions that the evidence for this is weak - has led to the development of a neurochemical model of NDE based upon the action of this psychoactive substance (Jansen, 1990, 1997a, 2001). A dissociative anesthetic - also reported to induce experiences of telepathy, precognition, clairvoyance, psychokinesis, communication with the dead, kundalini experiences and an increase in synchronicities (Case, 2003; Jansen, 2001; Luke & Kittenis, 2005; Wyllie, 1981) - ketamine acts by binding to the phencyclidine (PCP) site of the *N*-methyl-D-aspartate (NMDA) receptor, blocking the action of the neurotransmitter glutamate. Jansen indicated that potentially life-threatening circumstances (e.g., hypoxia, ischemia, hypoglycemia, temporal lobe epilepsy) can initiate a glutamate flood, which results in neurotoxicity through the over-activation of the NMDA receptors (for further details, see Smythies, 2011). This NDE trigger may be accompanied by a flood of neuroprotective agents that also bind to the NMDA receptors preventing damage, in much the same way as ketamine. Like Grinspoon and Bakalar's (1979) speculation that the brain synthesizes a chemical similar to ketamine in times of stress, Jansen proposed that "endopsychosins," which bind to the same receptor site as ketamine, would be discovered as the neuroprotective agents that cause an ASC, like that of ketamine, termed the NDE.

Although parsimonious, Jansen's (1997a) ketamine model of NDE has been both duly criticized and well defended. It has been argued that unlike NDEs, ketamine trips frequently induce fear (Strassman, 1997) and are not considered "real" (Fenwick, 1997). However, as Jansen (1977b) likewise contested, it is becoming increasingly recognized now that NDEs are also commonly reported to be distressing or traumatic (Atwater, 1994; Montanelli & Parra, 2000) and, furthermore, ketamine experiences are also more often than not reported to induce a sense of peace and pleasantness (Corazza, 2008; Luke, 2007). In support of the perceived reality of the ketamine experience, there are documented accounts of people who have had an NDE and then later a ketamine experience, and who reported the experiences being the same (Jansen, 2001). In support of this, Grof (1994) found that several cancer patients had NDEs during psychedelic therapy (most likely with LSD) that were very similar to later spontaneous NDEs.

In further criticism of Jansen's model, it has been argued (Fenwick, 1997; Greyson, 2000) that the clarity and clear memory of the NDE experience is not consistent with cerebral dysfunction. However, it is arguable that Jansen's model does not stipulate the necessity of cerebral dysfunction for a NDE, merely the threat, or even just the perceived threat of it, and Jansen (1997b, p. 87) pointed out "there is no reason to suspect that the NDE mechanism would never be activated spontaneously." Furthermore, Jansen (1997b) regarded clarity of consciousness as a nebulous term in the discussion of altered states, as the term is loaded towards the ordinary state of consciousness. Some researchers (e.g., Greyson, 2000; Smythies, 2011) have further contested that, despite the possibility that the endogenous peptide alpha-endopsychosin is a candidate, no endopsychosins have yet been identified or proven to exist, and Jansen (2001) conceded that this may initially have been a false lead and has suggested a number of alternative endogenous NMDA antagonists as candidates: N-acetylaspartyl-glutamate, kynurenic acid and magnesium, all of which protect brain cells from excito-toxic damage (Jansen, 2004). Nevertheless, Thomas (2004), following Jansen in his search, has identified technical flaws with these speculated endogenous "NDE-ogens" and has instead proposed the neuromodulator agmatine as the most likely candidate. The debate continues.

In further criticism of the model, Parker (2001) noted that one-drug/one-experience theories were abandoned in the 1970s and that, along with Greyson (2000), he further noted that ketamine appears to have multiple effects in the brain and multiple experiential features, some of which include those of the NDE. Jansen (1997b) earlier countered this latter criticism with the proposal that factors of set and setting are paramount in determining experience with all ASCs, be they NDEs or ketamine-induced states, so experiences are expected to vary. Parker (2001), like Siegel (1980), added that other drugs also produce features of the NDE, although Jansen (1997b) has asserted that these NDE-features are typical with ketamine but are not typical with other drugs, except for PCP and ibogaine (Bianchi, 1997; Jansen, 2001) which are NMDA antagonists (or more specifically called NMDA-PCP receptor blockers).

However, in support of Parker's (2001) criticism, Roll and Montagno (1985) have noted the similarity between NDEs and LSD experiences, as reported by Grof (1994). Reports of NDE also occur with the use of other dissociatives, like dextromethorphan (DXM) (White, 1997), and carbogen (Meduna, 1950), as well as with high doses of hashish (Siegel & Hirschman, 1984), and tryptamines like 5-MeO-DMT (Shulgin & Shulgin, 1997) and the ayahuasca (meaning "the vine of the dead") derivative, DMT (Strassman, 2001). Yet, Strassman (2001) did not find Jansen's model incompatible with his own DMT model of NDE, but rather asked why a neuroprotective agent like ketamine should also be psychedelic as there is no obvious benefit to the near-death visionary experience, other than enabling consciousness to have awareness of its departure from the body.

Recently, electrophysiology and receptor studies have revealed that both NMDA antagonists, such as ketamine, and classic hallucinogens, such as LSD, may actually enhance glutamatergic transmission via non-NMDA receptors in the frontal cortex. This may indicate a common mode of chemical action in the brain responsible for such similar experiences with these divergent molecules, though further investigation is required (Vollenweider, 2004). Given the similarities between NDEs, ketamine experiences, and other drug experiences, Rogo (1984) proposed that the NDE-like effects of ketamine are more often interpreted as NDEs because it has so often been used in a medical setting, further suggesting that ketamine-induced NDEs are less prevalent with recreational use than with anesthetic use, though this has not been systematically investigated to my knowledge.

To the author's knowledge, the only systematic investigation of the ketamine hypothesis, besides Jansen (2001), is that of Corazza (2008), who compared 36 cases of apparent NDEs induced by ketamine with 36 cases of NDEs reportedly caused by a cardiac arrest or other life threatening circumstances. Both groups showed a high degree of similarity in certain experiential features, with a roughly equal prevalence among the groups of experiences involving altered perceptions of time, speeded up visions, and the occurrence of ESP (25%), but the ketamine group were more likely to report unity with the universe, and the cardiac groups were more likely to report dissociation from the body, visions of light, and encounters with deceased or religious beings. However, Corazza asserted that the evidence indicates that NDEs can be induced through ketamine, although they may not be identical to those occurring naturally.

The study is not without its limitations; however, as outlined by Luke (2009), as the ketamine participants were recruited on the premise that they felt that they had had an NDE on ketamine, which Jansen (2001) reported only occur to about 12% of ketamine users. Furthermore, it is unclear if the respondents are describing a specific ketamine experience or an experience more generally, as most of the respondents had taken ketamine between 10 and 2000 times, though a similar number of cardiac arrest experiences is very unlikely for the comparison group. Nevertheless, Corazza and Schifano (2010) acknowledged the limitation that their findings are based on a self-selected, nonrandomized, limited size sample. Subsequently, ketamine can at best be thought of as an occasional NDE trigger or mimic, but is not a wholly repeatable or reliable source of NDEs (Luke, 2009). Nevertheless, cardiac arrest and the experience that ketamine invokes appear to be similar enough to genuine NDEs that leading consciousness researchers Hameroff and Chopra (2010) have called for its use in prolonging end of life brain activity (by delaying neurotoxicity) to allow terminally ill patients to have more conscious deaths.

More recently, having first researched the parapsychological potential of psychedelics in the 1940s, Smythies (2011) identified several apparent flaws with Jansen's K-NDE model. First, an NMDA-antagonist model of NDE is too general because the glutamate receptors can be found in all regions of the brain and yet the NDE phenomena suggest the activation of only specific brain regions, and furthermore ketamine does not appear to produce global brain NMDA-antagonism (although this latter point may argue against the first). Second, ketamine, Smythies argued, cannot actually stimulate the action potential of the neurons it binds to, but rather affects the modulation of the strength and number of synapses (i.e., the neuroplasticity), so it cannot immediately affect the brain regions required to stimulate the NDE. This second argument, however, seems somewhat contradicted by the phenomenological evidence that suggests that ketamine *can* in fact stimulate NDE-like phenomena and so presumably *does* activate the appropriate brain regions, at least indirectly.

Finally, Smythies (2011), contested that if the NMDA-antagonism explanation for NDEs were true, one would expect to see a relationship between NDEs and *grand mal* epilepsy - during which massive cerebral glutamate overload occurs. However, according to Smythies, the relationship is only apparently reported by one study (Britton & Bootzin, 2004), and is in any case weaker than the relationship between epilepsy symptoms and disturbed sleep patterns, although, in argument against Smythies, this weaker relationship may be accounted for by the infrequent occurrence of NDEs relative to sleep disturbances. Furthermore, counter to Smythies' conjecture, several other researchers have speculated about the link between NDEs and temporal lobe epilepsy, drawing parallels (Blanke & Dieguez, 2009; Jansen, 2001; Morse, Venecia, & Milstein, 1989; Neppe, 1989; Persinger & Makarec, 1987; Saavedra-Aguilar & Gómez-Jeria, 1989), although admittedly the NDE-epilepsy link is incomplete (Neppe, 1989), and epilepsy might best be thought of as one of several possible NDE triggers, as Jansen (1997a) originally proposed, rather than an explanation for NDEs. Ultimately, Smythies (2011) proposed that the excitatory NMDA receptor system, which runs continuously even while asleep, actually *is* the Bergson brain filter mechanism (discussed earlier in section 1.1) that ordinarily prevents people from experiencing what Aldous Huxley (1954, p. 11) called "Mind at Large": mystical and paranormal consciousness (i.e., an NDE). Consequently, Smythies asserted that NDMA antagonism, such as via ketamine or a natural NDE, bypasses the brain's natural filter action, leading to all manner of paranormal and transpersonal experiences. Much as Smythies should be applauded for morphing the two theories together, the same might be said for psychedelically induced serotonergic action as for glutamatergic action, so in effect this says little more than what Huxley originally proposed and what is now known about psychedelic neurochemistry (see section 1.1).

Overall, despite over simplification and generalization, the ketamine model of NDE offers the most complete neurochemical explanation of the NDE so far and, as with the DMT model, does not necessarily assume a materialist reductionism to explain the data - unlike Siegel (1980) for example - although some commentators (e.g., Sakellarios, 2005) have erroneously assumed that it does. Furthermore, the model can be easily tested and refined. For instance, there is evidence to suggest that the non-competitive antagonism at the non-glycine site of the NMDA receptor in particular is linked to the event of dissociative anesthesia and altered sensory perceptions that are familiar to ketamine. This would indicate that relatively novel substances like HA-966 (1-hydroxy-3-amino-pyrrolidone-2), which acts in this particular neurochemical manner (Bonta, 2004), could induce NDEs in blind conditions comparable to those occurring ordinarily, though this remains to be seen. In research with monkeys, HA-966 induced EEG patterns characteristic of sleep despite the animals remaining completely alert, which may be related to Jansen's (2004) observation that the same 60% of the population that do not recall their dreams also do not recall their ketamine experiences during anesthesia, a proportion apparently equivalent to the number of people who do not report having had some kind of NDE. Alternatively, in order to test the K-NDE theory, it has been suggested to administer ketamine to those who have had a natural NDE and compare the two (Kolp *et al.*, 2007). Assuming ketamine NDEs to be genuine, ultimately, however, the question remains of whether chemically induced NDEs utilize alternative pathways or the actual NDE pathway (Fracasso & Friedman, 2011).

Bringing personal observations (Luke, 2005) to the K-NDE debate, it seems apparent that the degree of general anesthesia induced by ketamine is relative to one's motor control ability and what Grosso (1976) identified as the degree of being out-of-body: Factors that are more pronounced with the positive S-isomer of ketamine rather than the negative isomer (Domino & Warner, 2010), further indicating how entwined these effects are, specific as they are to just one ketamine molecule type. Such relationships between sensory and motor impairment and reported body image have elsewhere been found with local anesthesia (Paqueron *et al*., 2003), though obviously not full blown OBEs. Returning to the personal observations, in repeated ketamine experiences I observed that the initial stages of anesthesia and out-of-body-ness are accompanied by increasing difficulty in controlling one's body and a growing sense of body dysmorphia, in a non-clinical sense, in that part of one's body may appear longer (macrosomatognosia) or shorter (microsomatognosia), as described by Frederiks (1963). For example, on one occasion I recall being unable to successfully maneuver out of the door because my legs appeared to be the approximate distance of an entire football pitch away. It is observed that the relatively changing gradation in increased anesthesia, body dysmorphia and motor control continues, with a sufficient dosage, as the trip intensifies towards a full-blown out-of-body experience, total anesthesia, and ultimately no motor control.

Indeed, while some K-OBEs are accompanied by autoscopy, even awareness of one's body can disappear at the peak of a high dose ketamine experience, even to the point of not realizing one actually has a body but instead just experiencing the present as a single point of consciousness and nothing more. On one such occasion I was seemingly privileged to a view of earth from space and yet I did not even know who or what I was, let alone that I was human and apparently had a body. This relatively changing relationship between anesthesia, motor control, out-of-body-ness, and even body-ownership-awareness is apparent on both entering and exiting the ketamine experience, although seemingly more so in exiting (although in reverse), as the entrance to a ketamine experience can often be abrupt, with a swift and intense onset, whereas the departure is more gradual. Such first-person psychonautics can report a good deal about both psychedelic states, especially ketamine states (Newcombe, 2008), and parapsychological phenomena (Luke, 2011c) and such methods are witnessing somewhat of a revival after a long hiatus since the era of William James' (1902) classic experimentation with nitrous oxide, another NDMA antagonist. Survey research also shows that ketamine induces OBEs and autoscopy far more often than other (non-anesthetic) psychedelics (Wilkins, Girard, & Cheyne, 2011), as had been previously speculated (Luke & Kittenis, 2005), the question remains of why anesthesia should accompany an OBE/NDE: Does the anesthesia cause the perception of being out of one's body, and therefore leads to a feeling of dying or of having died, or does the near-death experience provoke an OBE and subsequent anesthesia as a defense against likely pain? Observing the ketamine experience from the recipient's perspective, it appears that the anesthesia occurs because one's consciousness is no longer connected to one's body, and certainly the OBE and anesthesia are intimately connected, but why and how deserve further investigation and may shed light on the neurobiological factors of OBEs and NDEs.

1.5 Dopamine and paranormal beliefs and experiences

Taking a purely materialist reductionist view of paranormal experiences by attempting to account for them exclusively in terms of beliefs arising from faulty cognitions - what Irwin (2009) called the cognitive deficits hypothesis - a loose neurobiological model for the explanation of paranormal beliefs has arisen that posits the dopamine neurotransmitter system as the primary facilitator. Put forward by Krummenacher and colleagues (Krummenacher, Brugger, Fahti, & Mohr, 2002; Krummenacher, Mohr, Haker, & Brugger, 2009) the theory suggests that, although activity of the endogenous neurotransmitter dopamine is classically implicated in *enhancing* cognitive and perceptual decisions by improving the signal to noise ratio of neuronal transmission, paradoxically, hyperdopaminergic activity is associated with psychotic symptoms, schizophrenia and even schizotypy (for a brief review, see Krummenacher *et al*., 2009), and so excess dopamine may be accountable for delusional thinking stemming from an increased tendency to find patterns in apparently random data - what the psychiatrist Klaus Conrad (1958) called apophenia. According to Brugger and colleagues (e.g., Pizzagalli, Lehmann, & Brugger, 2001) paranormal believers - and so most likely paranormal experiencers too - have been shown to be more inclined towards apophenia than skeptics, thereby accounting for the increased creativity apparently associated with paranormal thinking and its similarity to some psychotic symptoms: a combination of creative and delusional dimensions being indicative of the positive phenomenology of schizotypy (Eckblad & Chapman, 1983).

Direct research into what might be most accurately called the hyperdopaminergia-apophenia hypothesis is somewhat limited at this time, consisting of only two studies, with somewhat mixed results. The first study

(Raz, Hines, Fossella, & Castro, 2008) attempted to relate paranormal belief as a phenotype to hyperdopaminergia as a genotype via what Raz *et al*. (2008) called the "COMT dopaminergic gene" (p. 1336), building on preliminary findings in behavioral apophenia dopamine research by Krummenacher *et al*. (2002) and studies associating schizotypy with dopaminergic genes (e.g., Avramopoulos *et al*., 2002). COMT (Catechol-O-methyltransferase) is an enzyme that degrades catecholamines such as dopamine, and the COMT protein is encoded by the COMT gene. Utilizing questionnaire measures of paranormal belief, 107 psychology students were genetically screened for three COMT allelic forms, successfully identifying approximately one quarter of the sample with high COMT activity, a quarter with low activity, and half with intermediate activity. However, failing to support the hyperdopaminergia-apophenia hypothesis those with decreased COMT activity, and hence greater hyperdopaminergia, reported no more paranormal beliefs, abilities or experiences than the higher COMT activity participants. Undeterred, Raz *et al*. (2008) pointed to the observation that attempting to unravel links between single gene polymorphisms that influence neurochemical function, and consequently individual differences in cognitive function, may be difficult when using distal phenotypes such as questionnaire measures, and that more proximal measures like brain imaging might be more promising. Indeed behavioral genetics is in a state of epistemological crisis after the lack of hard findings from the recently completed Human Genome Project (e.g., see Maher, 2008), so it may well be too soon to expect good data relating paranormal beliefs to genes, particularly single genes, even if they are related.

The second study, by Krummenacher *et al*. (2009), sampled 20 paranormal believers and 20 paranormal non-believers and administered levodopa - an active precursor to dopamine in the brain - in a randomized placebo controlled between-subjects study. Participants were given two signal detection tasks, one with words (tapping left hemisphere processes) and one with faces (right hemisphere), that presented either word/non-word or face/non-face stimulus pairs tachistoscopically for just 140 milliseconds. Participant responses were assessed for both their tendency to make correct guesses relative to incorrect ones, their sensitivity index (*d*'), and their tendency to respond with a positive or negative bias, their response tendency (*C*), both measures being independent of each other. Findings indicate that skeptics had significantly greater sensitivity to signal detection than believers in the placebo condition but, contrary to expectations, increased dopamine lead to a significant *decrease* in sensitivity in skeptics and had no effect on believers. These findings challenge the view that dopamine generally assists in signal detection, and Krummenacher *et al*. (2009) suggested that the opposite may actually be true in some cases, especially with presumed *hypo*dominergic individuals (i.e., skeptics). Additionally, the authors argued that the lack of change in sensitivity in believers administered levodopa may be due to a plateau effect caused by high cerebral dopamine baseline levels; however, such a suggestion is somewhat *post hoc* and, even if it were true, the authors do not comment on why the dopamine-enhanced skeptics had lower sensitivity (i.e., greater sensory apophenia) than either believer group.

Whereas the sensitivity measure findings are puzzling, the response bias measure results are somewhat more straightforward, in the control scenario at least. As was expected, in the placebo condition believers had a greater tendency to respond in the affirmative (favoring a Type I error strategy), whereas skeptics had a greater tendency to respond in the negative (favoring a Type II error strategy), the difference between the groups being significant. However, against expectation, in the levodopa condition these tendencies in each group were diminished so that there was no significant difference between skeptics and believers, although the trend remained. Specifically, compared to their placebo controls, dopamine-enhanced believers were more cautious of making false positive decisions (i.e., more conservative), and skeptics were less prone to make false negative decisions (i.e., more liberal), so that in effect both believer groups were less polarized in their responses. Contrary to the linear dopamine-apophenia relationship originally proposed, these results may indicate differing baseline dopaminergic activity in skeptics and believers and the possibility that there is a non-linear relationship between task and dopamine levels, perhaps an inverted U-shape, possibly modulated by individual differences in belief. However, these findings should be replicated first and more direct measures of baseline dopamine (e.g., spinal dopamine metabolic marker assay) should be made before these findings and *post hoc* interpretations are given much weight. Furthermore, as the authors noted, use of a between- rather than within-subjects design is far from ideal, leaving too much faith in the randomization of the small groups and no certainty in equivalence of baselines in dopamine responsivity and behavioral performance, and so further studies would benefit from a cross-over design.

Aside from the current lack of research on the hyperdopaminergia-apophenia hypothesis and the somewhat confusing mixed results, this line of research seems worthwhile pursuing further, although it suffers from additional limitations. One is that it aims to boil down paranormal experiences to misperceptions and misjudgments of the pattern recognition type, which, even if one allows for the fact that the authors *a priori* preclude the possibility of genuine paranormal phenomena, this approach does not account for the swathe of other cognitive deficits that are also given to account for paranormal beliefs, such as poor judgments of probability and randomness, egocentric bias, selective remembering, confirmation bias, and more (Brugger & Mohr, 2008). Indeed a study investigating probability inferences in those under the influence of ketamine, versus matched controls and schizophrenic patients, shows that the ketamine group were no different from the placebo group, whereas the patients were shown to exhibit a jump-to-conclusions response concerning probability inferences (Evans *et al.*, 2012). Although ketamine is primarily an NMDA-antagonist, it also has direct effects on dopamine receptors (e.g., Kapur & Seeman, 2002), and so the lack of probability inference effect with ketamine does not complement a dopamine explanation for paranormal experiences within the cognitive deficits paradigm. Other psychological factors supposedly related to paranormal experiences, such as the propensity for false memories, also show no relationship with self-reported recreational drug use generally (Wilson & French, 2006).

So in this respect the dopaminergic approach does not currently incorporate many of the multitudinous psychological explanations for paranormal beliefs and experiences. Furthermore, the wealth of evidence, to follow, relating increased paranormal experience - and to some extent experimentally controlled production of ESP - to the ingestion of psychedelic substances does not particularly support a dopamine-based theory of paranormality either, as dopamine activation is neither primary nor ubiquitous with psychedelic substances. Typically, classic tryptamine psychedelics (such as LSD and psilocybin) are thought to exert their effects via serotonin activation, particularly via the 5-HT$_{2A}$ receptor subtype (Lee & Roth, 2012). Nevertheless, it is thought that 5-HT$_{2A}$ receptor stimulation can activate dopamine release (Diaz-Mataix *et al.*, 2005), and Previc (2011) asserted that all the various psychedelic neurochemical pathways to "altered states of consciousness with distorted reality" (p. 43) ultimately lead to elevated levels of dopamine in the brain, although such reasoning rather ablates the intricate nuances of psychopharmacology and disregards primary neurochemical pathway activation as in any way important. Furthermore, although some psychedelic substances (e.g., LSD, psilocin, DMT) do have relatively high affinities for certain dopamine receptors (Ray, 2010), dopamine is rarely considered to be a primary neurotransmitter site for psychedelic effects. Indeed, the primarily dopaminergic recreational drugs, such as amphetamine and cocaine, have been found to be either unrelated or negatively related to paranormal experiences and beliefs (for a review see Luke, 2008b; and see section on survey data, to follow), contradicting the dopamine-paranormal belief/experience hypothesis. Indeed, if Previc were right about psychedelics exerting their effects via the dopamine system, then one would expect amphetamine and cocaine to be psychedelic too, which they are not.

Furthermore there are numerous psychedelics strongly associated with paranormal experiences that do not have dopaminergic action, such as the k-opioid agonist salvinorin A (Ray, 2010) and anticholinergic agents like scopolamine and hyoscyamine - which are found in nightshade family plants like datura (Katzung, Masters & Trevor, 2012). Overall - with scant direct research, mixed and complex findings, and poor generalizability of the hypothesis to a) other psychological explanations and b) most of the psychedelic-parapsychology literature - at the present time, Krummenacher, Brugger, Mohr, and colleagues' (Krummenacher *et al.*, 2002; Krummenacher *et al.*, 2009) dopamine-apophenia conjecture remains very much rudimentary and unsupported.

1.6 Overview of psychedelic/neuro-chemical models of paranormal experience

The preceding sections outline five neurochemical models germane to explaining psychic experiences, namely the brain as filter, β-carboline and tryptamine, DMT, ketamine and, finally, dopamine models. Aside from the latter, all of these models draw upon the action of psychedelic substances in particular and remain open to the possibility that psi and other so-called paranormal phenomena may be genuine. It should be noted, however, that no one psychedelic model may ultimately be the correct one, as psychedelics may work in many ways (e.g., dissociatives are both NMDA antagonists, as well as mu-opioid agonists); nevertheless these models provide important avenues for future research and begin to help develop more complete neurobiological models of apparent paranormal cognition or merely paranormal belief, and, indeed, more complete models of consciousness itself. The importance of understanding the apparent paranormal effects of psychedelics is clear and the evidence in support of this relationship is next reviewed and evaluated.

2. Field Reports of Paranormal Phenomena

2.1 Anthropological and Historical Reports

Despite apparent prejudices by anthropologists against reporting such phenomena traditionally (Winkelman, 1983), the anthropological and ethnobotanical literature remains replete with examples of ostensibly paranormal phenomena occurring with the traditional use of psychoactive plants. Commonly these plants are taken in ritual context for the express purpose of accessing altered states conducive to clairvoyance, precognition, telepathy, out-of-body travel, psychic diagnosis, psychic healing, and spirit communication, which provoked the mycologist Wasson (1964) to label them as the keys to extra-sensory perception. Archaeological evidence suggests such practices have existed the world over for millennia (see Devereux, 1997). However, the paranormal effects of particular plants are not necessarily arbitrary. Shamans who use the ayahuasca brew in Amazonia report having control over whichever particular paranormal function the brew elicits through the discerning use of psychoactive admixtures that may "make you travel, make you see" or "teach you to heal" (Andritsky, 1989, p. 78). Indeed, when the harmala alkaloid harmine, the first psychoactive compound isolated from the ayahuasca decoction, was discovered by Guillermo Fischer Cárdenas in 1923 it was named "telepathine" (Beyer, 2009) because of its apparent psychical properties, as reported by Zerda Bayon (1912). Zerda Bayon illustrated this with the case of Colonel Morales who, after ingesting ayahuasca, beheld a vision of his dead father and his sick sister. About one month later he received the same news by messenger. It seems unlikely that the news could have arrived first by nonparanormal means, as the group was deep in the jungle 15 days' travel from the nearest communications outpost.

Clairvoyant states induced with the harmala alkaloid-containing *Perganum harmala* shrub in Morroco have also been reported (Rudgley, 2000). Additionally, there are many more accounts of such apparent ESP with ayahuasca reported in Luna and White's (2000) anthology of classic ayahuasca experiences, as well as elsewhere (e.g., Beyer, 2009; Bianchi, 1994; Dobkin de Rios & Rumrrill, 2008; Gorman, 1992; Kensinger, 1978; McGovern, 1927; Shanon, 2002; Weil, Metzner, & Leary, 1965; Wilson, 1949). Typically, the earliest reports from explorers and anthropologists of the Upper Amazon were of either OBEs or experiences of someone discovering via visions that some distant person known to them, usually a relative, had just died (Luke, 2010a). In addition, Naranjo (1967, 1973) gave harmaline to 30 naïve urban elite Chilean participants who inexplicably reported the same images of snakes and jaguars, or big cats, as are commonly reported in traditional South American ayahuasca visions (Naranjo, 1987; Shanon, 2002). Visions of jaguars and snakes with harmaline have also been reported elsewhere (Shulgin & Shulgin, 1997) and one second-hand story from late sixties Haight-Ashbury (the temporal-spatial epicenter of psychedelic counter culture) proffered that someone once experimented giving ayahuasca to Eskimos and, devoid of the cultural milieu typical of ayahuasca use, they still saw huge cats in their visions, although it is unlikely that this research ever took place (Weil, 1980). Furthermore some of the participants in Naranjo's study were convinced they had seen these images by traveling out-of-body in time and space. Ott (1993) noted, however, that harmaline only occurs in minimal quantities in tested ayahuasca decoctions and so cannot be accountable for the psychoactive effects of the brew. Nevertheless, Strassman (2001) found that administering DMT (the most psychoactive constituent of ayahuasca) induced a similar certainty of space-time travel and resulted in the inordinately frequent occurrence of images of DNA, an image which Narby (1998) found commonly featured in the ayahuasca healing visions of Amazonian shamans, but was most often represented by snakes. It has recently been suggested, amid some controversy, that the geneticist Francis Crick was under the influence of LSD when he had a vision of the double helix structure of DNA in 1953, a discovery for which he was awarded the Nobel Prize (Rees, 2004).

Prior to this news report, which came after Crick's death, the anthropologist Narby (2000) took three molecular biologists to the Peruvian Amazon for their first visit there and for their first encounter with ayahuasca. The two female biologists both had encounters with plant teachers whom they perceived as independent sentient entities, and all three scientists received valuable information from their visions that helped inform their research, and which ultimately changed their world view. For instance, "the American biologist, who normally worked on deciphering the human genome, said she saw a chromosome from the perspective of a protein flying above a long strand of DNA" (Narby, 2000, p. 302). Similarly, the biochemist, Kary Mullis, who received the Nobel Prize for inventing the polymerase chain reaction (PCR) that significantly advanced DNA research, said that taking LSD had been invaluable in helping him experience the mental imagery that allowed him to visualize sitting on a DNA molecule to watch the polymerase go by (Mullis, 1998).

Further reports of the ritual use of psychoactive plants for the induction of paranormal abilities are commonplace among indigenous peoples from every inhabited continent. These range from the use of pituri (*Duboisia hopwoodii*) in Australia (Australian Institute of Parapsychological Research, 2004) to the use of San Pedro cacti (*Trichocereus pachanoi*) in Peru (Luke, 2012a; Sharon, 1990) and peyote cacti (*Lophophora williamsii*) in Mexico (Slotkin, 1956), *Amanita muscaria* mushrooms by the Ojibwa in Canada (Wasson, 1979) as well as suburban Muscovites and Siberian tribes-people in Russia (Ostrander & Schroeder, 1997; Wasson & Wasson, 1957), the use of datura among the Chumash of California (Driver, 1969), and the use of *Psilocybe* mushrooms (Stamets, 1996; Wasson, 1962) and *Salvia divinorum* by Mazatecs in Mexico (Soutar, 2001) to name but a few. Indeed, anthropologist Dobkin de Rios (1984, p. 60) has suggested that "the single most important function of plant hallucinogens in the Amazon area is to divine the future." Efforts to document the diversity of these traditional "shamanic" plants indicate there are about 100 distinct genera, let alone species, of such traditional plants that are reported to induce visionary states and are used ethnomedically (Schultes & Hofmann, 1992), with new ethnobotanical discoveries continually being made. However, few parapsychologists have conducted research with these plants or their users in their traditional environment, although with Wasson, Puharich (1959) attempted a remote viewing experiment with the *Psilocybe*-using Mazatecs in Mexico in 1955, but the experiment was aborted when instead Wasson and his co-expeditioner, Richardson, became the first researchers to be initiated into the mushroom cult. Nevertheless, Richardson (1990) reported personally having had an apparently precognitive vision, during what is documented as the first non-indigenous *Psilocybe* genus (i.e., "magic") mushroom trip.

A cross-cultural taxonomical study of shamans, shaman-healers, healers, and mediums, posits that, although these groups share many of the same characteristics, there is a clear division between those who do, and those who do not, use psychoactive plants and the differing paranormal activities they perform (Winkelman, 1989). Levine (1968) credited the botanist Schultes with the suggestion that the prevalence of vision-inducing plants among the herbarium of "primitive" societies is based upon a differing concept of illness, which has spiritual rather than physical causes. Contrary to Schultes, Winkelman suggested that the difference in the use of hallucinogens was due to cultural and developmental variances. Shamans from hunting and gathering societies and shaman-healers from agricultural subsistence societies both frequently use hallucinogens for the purposes of healing, divination, hunting-magic, and malevolent acts, whereas healers and mediums from sedentary and politically integrated societies as well as agricultural subsistence societies, do not use hallucinogens to access their altered states, which they use for healing and divination only.

Yet it appears that these cultural differences have occurred only recently in the developed world, as it has been suggested that the ancient Greek oracles, including the Pythia of Delphi - the seeresses that anteceded the divinatory Goddess Python - also used the *solanaceae* family of psychedelic plants (henbane, belladonna, mandrake, and datura) for divination (Masters & Houston, 1966; Parker, 1975; von Bibra, 1855/1994). Indeed the ancient Greek name for henbane was "pythonian" (Rudgley, 2000). It is also well documented historically that Northern European witches also utilized these plants for psychic purposes (see Andrews, 1997; Rudgley, 2000). Indeed, similarly to the Greeks, the Northern Europeans gave the name "alruna" to their visionary seeresses, in common with the German name for mandrake, "alraune," both of which stem from "rune," the Germanic divinatory letter system (Müller-Ebeling, Rätsch, & Storl, 2003). No doubt, the traditional Northern European practice of pharmacologically accessing visionary states all but died out with the witches during the Inquisition, between the fourteenth and seventeenth centuries (Grob & Harman, 1995). It is probable that a combination of changing concepts of illness, the development of a sedentary, politically integrated society, and the influence of the Inquisition or colonization were responsible for the virtual disappearance of the traditional indigenous use of psychoactive plants for paranormal purposes in Europe and North America.

At the end of the 19th century, pioneering psychological explorers in the West rediscovered the vision-inducing qualities of novel plant substances, such as mescaline (Ellis, 1898), whereas others explored new synthetic visionary chemicals like nitrous oxide (James, 1902), with some early psychical researchers dabbling in both (Dunbar, 1905). By the middle of the 20th century the Swiss chemist Albert Hofmann had discovered LSD - experiencing its OBE-inducing properties - and isolated, named, and synthesized psilocybin and psilocin, the psychoactive derivatives of the visionary *Psilocybe* mushroom genus (Hofmann, 1983; Luke, 2006). The ascribing of the word psi to psychic phenomena during this period, however, may only be a coincidence. By the turn of this millennium there were around 200 psychedelic compounds known to science, a figure estimated to likely rise to 2000 compounds by the year 2050 at the current rate of discovery, increasing exponentially by a factor of ten every fifty years, starting with the two that were known in 1900 (Shulgin, 2004, 2010). Despite the rapidly upwards bending curve of Shulgin's formula, current quantities may even exceed it, as a good guestimate puts the number of *potentially* psychedelic compounds now known to man at about 2000 (J. Hanna, personal communication, August 12, 2012), given that there are something like 1300 documented phenethylamine compounds alone (including substances like mescaline, MDMA, & 2CB) known at the current time (Shulgin, Manning, & Daley, 2011), though they may not all be effectively psychoactive and have not been sufficiently tested as yet. However, a conservative estimate would put the number of known, tried, and tested psychedelics at between 250 (J. Hanna, personal communication, August 12, 2012) and 300 to 400 (Shulgin, 2010). Furthermore, a more recent projection puts the total number of undiscovered drugs (not necessarily psychedelic) at 1×10^{60} (Reymond & Awale, 2012), more than visible stars in the sky, and so Brown (2012b) anticipated a near limitless number of psychedelic compounds to arise, especially when factors of nanotechnology, neurostructural engineering, and other technological advances are additionally considered. Nevertheless, Brown's projection is purely speculative, but it is safe to say that humans have not yet discovered all the psychedelic substances that will ultimately be available, and that there may be many more to come, and, with each one offering a different type of ASC, there remain many states yet to be discovered. Brown (2012b) even fancied that specific psi-inducing psychedelics may be intentionally engineered in the future.

2.2 Personal Views and Experiences

Since the discovery of psychedelic compounds by the academic community and their popularization among the intelligentsia by the novelist Aldous Huxley (Smythies, 1960), there has been a steadily growing number of reports of paranormal experiences occurring with the use of these compounds. Several parapsychologists and psychical researchers, primarily from the 1950s and 1960s when psychedelic research was at its peak, have endorsed the research of psi with psychedelics (e.g., Assailly, 1961; Broad, 1962; Hoffer, 1961a, 1961b; Johnson, 1955; Kern, 1964; Laidlaw, 1961; Paterson, 1961b; Price, 1948; Thouless, 1960; Tibbs, 1963; West, 1965). Even J. B. Rhine, the father of modern parapsychology, ran some informal psychedelic sessions in 1961 at the Rhine Research Centre in Durham with the then Harvard psychologists Timothy Leary and Richard Alpert (Black, 2001; Horn, 2009; Stevens, 1988), although there was apparently too much spontaneous laughter erupting for anyone to credibly test for anything (S. Abrams, personal communication, August 14, 2006; S. Krippner, personal communication, January 19, 2006).

Notably, many other parapsychologists have reported personal ESP experiences with the use of LSD (Cavanna, 1961; Garrett, 1961b; Millay, 2001; Osmond, 1961a; Servadio, in Alvarado, 1995), peyote/mescaline (Langdon-Davies, 1961; Millay, 2001; Osmond, 1961a), psilocybin (Cavanna, 1961; Krippner, 1967; Millay, 2001) *Amanita muscaria* (Puharich, 1962), and ayahuasca (Severi, 1996, 1999). Krippner's apparent precognitive vision of President Kennedy's assassination while on psilocybin serves as a good example (Krippner, 1967, 2006a). Though, of course, merely consuming a psychedelic is no guarantee that an experience of ESP will follow, as Price (1964) aptly demonstrated self-experimenting with mescaline. However, other psychical researchers, sometimes following their own experiences, have noted the apparent tendency for ESP production with the use of psychedelics, including no less than four Parapsychological Association presidential addresses (Dean, 1967; Heywood, 1978; Hastings, 1973; Luke, 2010b; Radin, 1989; Servadio, 1961; Stevenson, 1981). Furthermore, some have recommended that other psi researchers personally explore psychedelic states of consciousness to aid in their understanding of the concept of psi (Cavanna, 1961; Heywood, 1961). The most highly experienced LSD psychotherapist, Stanislav Grof (1980), also advised that an intimate knowledge of the transpersonal realms created by psychedelics is essential for parapsychologists. Personal accounts of ESP have also been reported by leading psychedelic mycologists (Stamets, 1996; Wasson & Wasson, 1957).

Beloff (1968) asserted that greater reporting of ESP on college campuses would have been evident if drugs induced psi particularly, to which Tart (in Beloff, 1968) replied that many students took paranormal events in conjunction with psychedelics very matter-of-factly, due to their prevalence. This point was further echoed by the suggestion that users of psychedelic drugs frequently report vivid ESP experiences but that they remain largely unpublished (Stafford & Golightly, 1967). Yet, Heywood (1961) found several incidences of psi with

LSD within the "well-evidenced" SPR spontaneous-case collection. However, more recently, Vayne (2001), echoing Tart, has suggested that among practiced users of psychedelics, dubbed *psychonauts*, the telepathic experience is so common that it is hardly remarked upon. Luke (2004c) agreed with Vayne but further offered that, even so, many (less well-evidenced) anecdotal reports could be found on contemporary resources on the internet. Psychedelic drug information sites (such as www.lycaeum.org and www.erowid.org) have amassed a large online archive of experiential psychedelic reports, among which are accounts of ESP experiences with substances as diverse as ketamine, *Salvia divinorum*, *Psilocybe* mushrooms, ayahuasca analogues, and 3,4-methylenedioxymethamphetamine (MDMA, or ecstasy) mixed with baby Hawaiian woodrose seeds, a natural source of lysergic acid (Anonymous, 2004a, 2004b, 2004c, 2004d, 2004e, 2005).

Similar reports of frequent ESP experiences with such substances from within the psychedelic community are also available elsewhere in the literature (e.g., Eisner, 1989; Gaskin, 1990; Krippner, 2006a; Krippner & Fersh, 1970; Lilly, 1967, 1978; McKenna, 1991; McKenna & McKenna, 1994; Millay, 1999, 2004a, 2004b, 2005, 2006, 2010; Osmond, 1968; Saunders, 1993; Scully, 2010; Stevens, 1989; Turner, 1994; Wyllie, 1999; Zelnick, 2005). Indeed, the notion of experiencing a telepathic group mind, or "tribal telepathic understanding" (Nuttal, 1970, p. 249) through "tripping" became so prevalent among the psychedelic culture of the 1960s that prospective psychedelic users were told they might expect such an experience (Leary, Metzner, & Alpert, 1964) and commonly it became known as "grokking" (Stevens, 1989; Wolfe, 1971). Currently, the same notion is still apparent among psychedelic users (e.g., MoDu, 2003) and the largest public-edited internet encyclopedia indicates that ESP-type phenomena are a common fourth-level experience on a five-level spectrum of psychedelic experience intensity (Wikipedia, 2005), though clearly this is not academically evidential but rather an indication of commonly held notions, among Wikipedia editors at least. Although notably, PK is seldom reported in the literature, save for the odd exceptional report (e.g., Shulgin, 2004), and it has been suggested among occultists that chemical agents are only useful for "receptive" magic/psychic purposes, such as traveling clairvoyance, divination, and spirit evocation or invocation (e.g., Carroll, 1987; Vayne, 2001; Xeper, 2005). The use of psychedelics for such magical purposes now appears to be growing in popularity among occultists and is seemingly far more prevalent within the literature than it used to be (e.g., see Louv, 2005; Kent, 2010).

2.3 Clinical

A review of the literature from the clinical setting reveals surprisingly few published psychiatric inpatient reports, although there are some epidemiological studies (see section 3.2.1) relating to psychedelics and paranormal experience. This may be due to any number of factors, such as the lack of any such spontaneous phenomena within the psychiatric population, or the medicalization within psychiatry of paranormal experiences as delusion or hallucination. Indeed, Mogar (1965) noted that early psychoanalytic and behaviorist researchers using LSD were prejudiced against ESP phenomena. Yet, there is one study, a psychiatric-interview survey with users of LSD (Abraham, 1983), that reports precognitive experiences as one of the symptoms of the LSD flashback phenomena, now called hallucinogen persisting perception disorder (American Psychiatric Association, 2000).

On the other hand, there are many accounts of paranormal experiences with psychoactive drugs from within psychedelic psychotherapy, particularly that involving LSD (Grof, 1975, 1980, 1990, 2001; Harman, 1963; Holzinger, 1964; Levine, 1968; Masters & Houston, 1966; Pahnke, 1968) and psychedelics in general (Eisner, 1995; Laidlaw, 1961; Stolaroff, 2004). Tart (in Levine, 1968), quoted the International Foundation for Advanced Study, which in the course of between 300 and 400 psychedelic therapy sessions has reported the incidence of ESP with strong evidence seven times, which is a considerably higher incidence of psi than that reported to have occurred in non-psychedelic psychotherapy (Tornatore, 1977a, 1977b). As one specific example of this line of research, the percentage of clients reporting telepathic communication during LSD-assisted therapy changed from 49% in the first psychotherapy session to 80% in the second session (Blewett & Chwelos, 1959).

The psychiatrist Stanislav Grof, generally credited with the most expertise in this field having conducted more than four thousand psychedelic therapy sessions over a two decade period, reported observing patients experiencing OBEs, ESP (particularly precognition), accurate remote viewing, and space-time travel on a daily basis (Grof, 1975, 1980, 2001). Despite acknowledging that there was a danger of data contamination and a difficulty of verification, Grof (1980) contended that the occurrence of ESP was relatively frequent and that LSD could induce states conducive to an unusually high incidence of ESP (Grof, 1975). Often the reports of telepathy could have been merely self-deception, but other times there was apparently objective verifiable communication at work (Grof, 1980). Grof further found the common occurrence of OBEs, both within and independent of this physical plane, often with traveling clairvoyance and clairaudience. There were also occasional NDE experiences reported (Grof, 1994). Most frequent was the occurrence of extraordinary coincidences or synchronicities, yet only among those clients who experienced transpersonal breakthroughs within the psychedelic session (Grof, 1980). Finally, Grof (1990) also reported two events, rare in the literature, of clients under LSD who experienced visions of the dead that provided apparently unknown, but verifiable information. One such event occurred to the wife of the late psychedelic-psychical researcher Walter Pahnke. During an LSD session, Mrs. Pahnke had a vision of her dead husband who requested her to return a book concealed in her attic. Although she claimed to have had no prior knowledge of the book, she managed to locate and return it. Of course, it is possible that the knowledge of the book already lay in her subconscious (Stokes, 1997).

One of the most astonishing reports of psi occurring within the clinical setting came from the psychiatrist Paul (1966), who reported taking the mushroom *Amanita pantherina*. This was her only psychedelic experience and was part of an ESP experiment being conducted by Puharich (see Puharich, 1959, 1962). Paul had an incredibly intense trip, complete with apocalyptic visions followed by salvation through overwhelming love, and was unable to complete the experiment. However, on return to her practice, two of her clients reported extraordinary events at the time Paul had been tripping. One patient had amnesia for the same three hours on Friday evening following the consumption of his first-ever (non-psychedelic) mushroom meal, and upon remembering his experience, recalled that he had experienced the same apocalyptic fears as Paul had experienced. The other patient could not remember what she had done that evening but on investigation discovered that she had gone to the house of a secret lover and waited outside, love-struck, for two hours, but was prevented from taking any irrational action by her friend, who later informed her of the event. Both patients had a strong bond with the therapist and had expressed an interest in ESP. Paul interpreted the event as a case of spontaneous telepathic tripping, complete with amnesia on the part of the receivers, perhaps demonstrating a certain unpredictability in the experimental induction of psi with psychoactive drugs.

2.4 Evaluation of Field Reports

In summary, there is a wealth of reports of the spontaneous occurrence of ostensibly paranormal phenomena with the use of psychedelic substances. Yet this does not mean that these experiences are necessarily genuine paranormal events: Aside from the usual arguments for and against spontaneous phenomena as evidence for the paranormal (e.g., see Pekala & Cardeña, 2000; Stokes, 1997), the fact that respondents had consumed a visionary substance may be reason to question their perception and interpretation of the experiences, at least for those cases which are not substantiated by evidence or independent observers. Nunn, Rizza, and Peters (2001) have found that cannabis use is related to delusional ideation, although it is not directly related to delusional conviction; however, the relationship between psychedelic use and the propensity for false memory and poor probability judgments has not been established (Kapur & Seeman, 2002; Wilson & French, 2006). Furthermore, Shanon (2003) pointed out that the usual definitions of hallucination in the psychological literature fail to adequately encompass the diverse and complex nature of experiences that occur with psychedelics, and nor can assumptions be made about the ontology of such psychedelic-induced visions. Indeed, many people who have had paranormal psychedelic experiences reported how real the experience seemed, often being felt as more real than the ordinary waking experience (e.g., Hofmann, in Grof 2004; Shanon, 2003; Strassman, 2001). It has also been reported that psychedelic-induced mystical experiences feel no less real than previous spontaneous mystical experiences (Doblin, 1991; Exman, 1961; Greeley, 1974; Griffiths, Richards, McCann, & Jesse, 2006; Pahnke, 1966; Pahnke & Richards, 1966; Roberts, 2001; Smith, 2000; Smith & Tart, 1998; Watts, 1968), the same being true for NDEs (Jansen, 2001).

In defense of drug-induced altered states, Devereux (1997) has suggested that, "it is a culturally engineered cliché to dismiss such states as being somehow delusional" (p. 243). Furthermore, Smythies (1960, 1983) has taken issue with the concept of dulled and hallucinatory psychedelic states and insisted that these hallucinations are more than just images from a poisoned brain. Additionally, LeShan (1968) has mocked the assumption that ordinary reality is somehow more real than the psychedelically induced ASC, whereas Tart

(1977) questioned how natural is the ordinary state of consciousness, built through a lifetime of socialization. Tart (1972, 1998, 2000, 2001) further questioned the idea that rationality only occurs in the ordinary state, and proposed the establishment of state-specific sciences (for further discussion see Walsh, 2003).

No matter what their epistemological status, however, these experiences do offer a phenomenological spectrum of evidence around which to orient further research. Furthermore, the similarity in reports between those occurring spontaneously in exploratory, therapeutic, and accidental contexts, and those induced intentionally in the traditional ritual context, gives credence to the shamanic use of these substances for supposedly paranormal purposes. By contrast, other traditional psychoactive substances, such as alcohol, coffee, and cocaine are not contemporaneously reported to induce spontaneous paranormal phenomena, and neither are there folk beliefs that suggest they do. Nevertheless, Rogo (1975) wondered whether the occurrence of psychedelic-induced ESP experiences exceeded that of normal ESP experiences, a question that may be partially answered by survey research.

3. Surveys

When reviewing the survey research one immediately notices two trends. First, virtually all of the surveys reported here were published since the 1970s, after the period when most psychedelic research was conducted and the unlicensed use of these drugs mostly became illegal in Europe and North America. Secondly, most of the following surveys have primarily focused on paranormal experiences or belief and have only recorded drug use information as one of many possible co-variables, often omitting to distinguish among the different substances. Only a few studies (DeGracia, 1995; Kjellgren & Norlander, 2000; Tart, 1993; White, 1997) have approached users of psychoactive substances as the target sample.

3.1 Surveys of Belief in the Paranormal

Investigating belief in the paranormal with the Mental Experience Inventory (MEI), Kumar, Pekala, and Cummings (1992) additionally utilized a sensation seeking scale that included a yes/no question about recreational drug use. Of an opportunity sample of 574 psychology students, drug users reported greater paranormal and psi-related beliefs; however, results were reported in terms of the larger sensation-seeking measure as significant main effects. In a more direct assessment of the relationship, Gallagher, Kumar, and Pekala (1994) transformed the MEI into the Anomalous Experiences Inventory (AEI; Kumar, Pekala, & Gallagher, 1994), adding a Drug-Use subscale to complement the other four subscales relating to Anomalous/Paranormal Belief, Experience, Abilities, and Fear. The AEI was successfully validated against other paranormal experience and belief scales using an opportunity sample of 400 psychology students. The AEI Drug-Use subscale correlated positively, although only very weakly, with the AEI Anomalous/Paranormal Beliefs subscale ($r = .16$, $p < .01$) and with Tobacyk's (1988) paranormal belief subscales: Belief in Psi ($r = .10$, $p < .05$), Belief in Witchcraft ($r = .12$, $p < .05$), Belief in Superstition ($r = .11$, $p < .05$), Belief in Spiritualism ($r = .17$, $p < .01$), Belief in Extraordinary Life Forms ($r = .13$, $p < .01$), but not Belief in Precognition. Drug use correlated negatively with Traditional Religious Beliefs ($r = -.14$, $p < .01$).

In addition, some items in the AEI Drug-Use subscale correlated with Tobacyk's (1988) Revised Paranormal Belief Scale, although only very weakly. Overall, paranormal belief correlated negatively with heroin use ($r = -.12$, $p < .05$) but positively with the use of LSD ($r = .11$, $p < .05$) and mind-altering substances ($r = .15$, $p < .01$). There were no significant correlations found for marijuana, cocaine, or alcohol. The same correlations were found between the AEI Anomalous/Paranormal Belief subscale and some AEI Drug-Use subscale items (mind altering substances, $r = .18$, $p < .001$; LSD, $r = .15$, $p < .01$), but also including marijuana ($r = .16$, $p < .01$), but not heroin. Additionally, for all categories of drugs except heroin there was a small significant negative correlation with the fear of psi (from $r = -.12$ to $-.24$), whereas alcohol use correlated positively with fear of psi ($r = .13$, $p < .05$). The lack of a consistent significant correlation between paranormal belief and marijuana use runs counter to Tart's (1993) finding that 76% of marijuana users believe in ESP. This difference may be due to cohort differences, such as culture and their reasons for using marijuana, or that Tart's marijuana sample were mostly also experienced with LSD (72%, with 36% classified as heavy psychedelic users; Tart, 1971), a drug that Gallagher *et al*. (1994) did find to be related to paranormal belief. Furthermore, it should be noted that the items of the AEI Drug-Use subscale only register nominal yes/no responses, whereas more sensitive ordinal drug-use measures would have been expected to demonstrate stronger correlations, if the relationships were linear. Nevertheless, correlations from this study reported here are uncorrected and should be accepted with some caution because of the use of multiple inferential tests.

Pekala, Kumar, and Marcano (1995a, 1995b) sought to find a relationship between the subscales of the AEI and measures of hypnotic susceptibility and dissociation on a similar opportunity sample of 413 psychology students. Supporting the Gallagher *et al*. (1994) study findings, the Drug-Use subscale correlated positively, and somewhat more strongly, with Anomalous/Paranormal Beliefs ($r = .25$, $p < .001$) as well as negatively with Fear of the Anomalous/Paranormal ($r = -.14$, $p < .01$), although no breakdown of the results for the Drug-Use subscale was given for the different substances. In addition, overall drug use was found not to correlate with dissociation or hypnotic susceptibility, although marijuana was a special case (see Pekala *et al*., 1995b).

A later opportunity sample of 107 students (Houran & Williams, 1998) were surveyed using the AEI to explore the equivocal relationship between belief in the paranormal and tolerance of ambiguity. Further support was demonstrated for the small but significant relationships between drug use and anomalous/paranormal belief ($r = .22$, $p < .05$) and fear of the anomalous/paranormal ($r = -.18$, $p < .05$). Tolerance of ambiguity was found to correlate minimally with both paranormal belief and drug use ($r = .23$, $p < .05$), and more so with psychedelic drugs (LSD, marijuana), rather than cocaine, alcohol, or heroin.

Simmonds and Roe (2000) used the AEI in relation to schizotypy, temporal lobe lability, and personality correlates with an opportunity sample of 145 psychology students. Similarly to previous surveys, there was a small significant correlation between drug use and anomalous/paranormal belief ($r = .20$, $p < .05$). Drug use was also found to relate to complex partial epileptic signs (CPES) as measured by a subscale of the Personal Philosophy Inventory developed by Persinger and Makarec (1987), which they had predicted would be the case. However, it is apparent that several items of the CPES are consistent with experiences often reported in other ASCs, drug-induced or otherwise, so such a correlation might be expected anyway. Furthermore, neither of these correlations remained significant when the alpha level was recalculated using a Bonferroni correction for multiple tests, although the relationship between drug use and belief remains consistent with these other surveys, so this correlation is probably genuine, albeit small.

A later survey (Thalbourne, 2001) using the AEI sought to replicate the relationship found by Gallagher *et al*. (1994) between drug use and belief in the paranormal, and in addition investigated this relationship with respect to transliminality and to kundalini experiences. Transliminality was measured using the 29-item Transliminality Scale (Thalbourne, 1998), before it was rasch-scaled for age and gender bias. Using an opportunity sample of 125 psychology students, Thalbourne found a small significant positive correlation between the AEI subscales: Drug-Use and Anomalous/Paranormal Belief ($r = .24$, $p < .01$), supporting previous findings. There was a suggestive but non-significant negative correlation between drug use and fear of the anomalous/paranormal. There was also a significant positive correlation between drug use and transliminality ($r = .29$, $p=.001$) and the New Age Philosophy (NAP) subscale of the Tobacyk's (1988) Revised Paranormal Belief Scale ($r = .23$, $p < .01$). There was, however, no significant correlation with Tobacyk's Traditional Paranormal Beliefs (TPB) subscale, and reanalysis of Thalbourne's data by Houran and Lange (2001) found the difference in reports of drug use in relation to NAP and TPB to be significant ($p < .001$, uncorrected for multiple analyses), reinforcing their argument for two distinct paranormal belief groups. Furthermore, drug-use did not correlate with Thalbourne and Delin's (1993; non-rasch scaled) Australian Sheep-Goat Scale, a different paranormal belief scale (Thalbourne, 2001).

These findings partially support Gallagher *et al*.'s (1994) small positive correlation of drug use with the Tobacyk Belief in Psi subscale, yet to what extent is not discernable because Thalbourne's (2001) results were reported in terms of just two collapsed subscales rather than the full seven. The same is also true of correlations between Anomalous/Paranormal Belief and the Drug-Use subscale, although of note, very few respondents used heroin ($n = 3$) and cocaine ($n = 6$) compared to LSD ($n = 26$) or marijuana ($n = 61$), indicating that correlations with those reporting drug use ($n = 57$, obviously some of the respondents did not consider marijuana to belong to this category) were largely in terms of psychedelics rather than other drugs.

A *post hoc* analysis of the relationship between transliminality and drug use revealed there were small, but significant, positive correlations (ranging from $r = .20$ to $.27$) between transliminality and all of the AEI drug-use categories (mind-altering substances, marijuana, LSD, cocaine, and heroin) except for alcohol. Thalbourne (2001) suggested that this relationship may be due to the need to use drugs to escape the unpleasant aspects of the transliminal state, or that drug use may be a means of promoting the psychic phenomena of which high transliminal scorers may have become deprived. Both of these hypotheses might prove to be somewhat correct, but only for differing substances. It is highly unlikely that psychedelic drugs are used to escape the transliminal state because these substances are actually more likely to cause the opposite effect, although some non-psychedelic drugs, such as opiates/opioids might help to escape transliminality. Indeed, Vayne (2001) has suggested psychedelics are expressly used to access liminal states. Alternatively, Thalbourne has speculated that an "openness to experience" trait underlies the relationship between drug use, transliminality, and paranormal experience.

In a follow-up survey (Thalbourne & Houran, 2005), an opportunity sample of 200 psychology students completed the Revised Transliminality Scale (Lange, Thalbourne, Houran, & Storm, 2000), and an extended version of the AEI Drug-Use subscale, which included two extra items, one relating to ecstasy (MDMA) and one relating to speed (amphetamines). As previously, though somewhat less so, drug use was found to correlate marginally, although significantly, with transliminality ($r = .21$, $p < .005$, one-tailed). Furthermore, scores on the Oxford Happiness Questionnaire demonstrated that transliminality was not related to happiness and that the majority of high transliminals were happy, offering support to McCreery and Claridge's (1995) notion of the pathology-free "happy schizotype" prone to paranormal experiences. However, unhappy highscoring transliminals reported significantly more drug use than happy high-scoring transliminals ($t = 1.98$, $n = 77$, $p < .05$), somewhat supporting Thalbourne's (2001) speculation that transliminality, akin to psychosis, can be a unhappy state that such people attempt to escape from with drugs. Unfortunately, Thalbourne and Houran's findings sweep several different types of drugs - including psychedelics, narcotics, stimulants, and alcohol - together under one umbrella, revealing very little about which of these very different drugs relate to each particular syndrome. For instance, given the system of scoring in this study, it is easily possible that the use of just one drug, such as alcohol, entirely accounts for the differences in substance use between happy and unhappy transliminals, and further research begs more specific analyses.

Here Metzner (2005) pointed out that, aside from merely varying in how they activate or relax one's nervous system, psychoactive drugs may also be classified along a hedonic continuum of pain and pleasure, reflecting Thalbourne and Houran's (2005) simplified notions about drugs and the quest for happiness. However, taking a transpersonal approach, Metzner further indicated that drugs may also be considered along a third dimension of consciousness expansion and contraction, such that psychedelics are essentially conscious expanding, whereas opiates, alcohol, cocaine, and amphetamines, being focally restrictive and addictive, are consciousness contracting. Thus, a range of drugs can be used when seeking stimulation, sedation, or happiness, but only specific drugs, psychedelics, will lead to consciousness expanding experiences, and perhaps even ostensibly paranormal ones too. Arguments may prevail over precise definitions and classifications here, but the point remains that psychological research would most likely benefit from a recognition of the experiential differences between drugs rather than just a recognition of their legal status and a crude categorization of them based only on that (Friedman, 2006).

3.2 Surveys of Paranormal Experiences

3.2.1 Psychiatric epidemiological samples

Recently, a wealth of epidemiological psychiatric research has surveyed reports of cannabis use and schizotypal symptoms, finding fairly consistent correlations between them (for a review, see Castle & Murray, 2004). Items relating to telepathy and other kinds of thought broadcasting have been often included, and it deserves mentioning that the subscales in which theses items appear tend to correlate with cannabis use (e.g., Johns *et al.*, 2005). However, although relevant, this research is largely indirect to the present review as incidence rates for specific types of paranormal-like experiences are rarely reported, but rather form part of more general subscales.

More specifically, in a quasi-experimental design with 196 university students, Nunn, Rizza, and Peters (2001) found that cannabis use, but not alcohol use, was positively related to unusual experiences (such as the possession of special, almost magical powers), but use of either drug was unrelated to depression or anxiety. Furthermore, cannabis use was related to delusional ideation but not distress, further supporting the notion of the happy schizotype, although cannabis and alcohol use combined was related to delusional conviction. Nunn *et al*. suggested that schizotypal traits may predispose subjects to cannabis use or that cannabis use may result in high schizotypy scores. Although some prospective studies have been conducted in this area, there are often so many possible confounding factors involved in such research that directions and sources of causality remain entirely speculative (see Castle & Murray, 2004).

3.2.2 Clinical populations

Finding numerous paranormal experiences reported in a DXM-users survey (see section 3.2.4 to follow), White (1997) sought to explain the survey results in terms of temporal lobe dysfunction (TLD). Tentative indirect support comes from a survey of a convenience sample of 100 neuropsychiatric patients where a positive recreational drug-use response was used, among other measures, as a predictor of TLD, with TLD correlating well with reports of subjective paranormal experience (Palmer & Neppe, 2003). However, the recreational drug-use measure utilized a blanket definition that lumped together the use of a variety of different psychoactive drugs and moreover treated drug use alongside brain injury as causative factors in TLD, although there is no clear reasoning given for doing this. In this study, recreational drug use was taken to be either of the following: prolific marijuana use; the three times use of hallucinogens, LSD, mescaline, or PCP; or six months' use of heroin or amphetamine. However, it was reported in a later paper that, when gender was controlled, there were no relationships between subjective paranormal experiences and any of the categories of drug use or brain injury with this sample (Palmer & Neppe, 2004), although results may be due to underpowered statistics with only six respondents in this group.

3.2.3 General and student samples

Several major surveys of psychic experiences have included questions regarding the use of psychoactive drugs. The first series of surveys of this nature utilized a psychic experiences questionnaire created by Palmer (1979) for use in a randomly distributed postal survey. The questionnaire was completed by 354 townspeople (T) and 268 students (S), treated as different samples, with response rates of 51% and 89% respectively. Those who acknowledged the use of mind-expanding drugs also responded positively to being an ESP agent, having a recurrent spontaneous PK experience (T only, $p < .01$, although Palmer urged caution with these two results because of low responses), haunting experience (T only, $p < .05$), aura vision (S, $p < .05$), and OBEs (S, $p < .01$). Despite reported drug-use differences between samples, equal proportions from each group (T: 29%; S: 28%) reported psi experiences actually occurring during use. Kohr (1980) criticized the analysis for not reporting the chi-squared statistic and for using an underpowered test.

Kohr (1980) surveyed a special sample of self-selecting respondents ($n = 406$) from the Association for Research and Enlightenment, an organization whose membership represented those intrigued by the legacy of the renowned psychic and Christian mystic Edgar Cayce. Using Palmer's (1979) questionnaire, Kohr failed to find any association between subjective paranormal phenomena and the use of mind-expanding drugs, although figures for drug use were not actually reported. It is suspected that the drug use statistics were not reported in this study because its incidence was quite low. The Kohr sample was both older (61% over 40 years) and markedly more religious (40% = very religious) than the Palmer samples (over 40 years, T = 51%, S = 0%; very religious, T = 8%, S = 9%), and, as stated earlier, Gallagher *et al*. (1994) found traditional religious beliefs to correlate negatively with drug use. Roney-Dougal (1984) surveyed a different special sample, attendees at an occult conference, about their psi experiences. Of the 33 respondents, 30 (91%) reported psi experiences, of which 12 (40%) reported the use of mind-expanding drugs. This indicates both the slightly higher reported use of psychedelics (36% of the sample) and the greater reporting of paranormal experiences among occultists compared to other populations, though this observation may not be reliable.

Another survey (Usha & Pasricha, 1989a, 1989b) modified Palmer's (1979) questionnaire, particularly the demographic questions, to suit the needs of an Indian student population ($n = 328$; response rate 79% using opportunity sampling). Use of mind-expanding drugs was reported by 11%, who were also significantly more likely to be Hindu ($p < .05$) or male ($p < .01$), probably largely due to the sacred use of marijuana among many Indian men, mostly Hindus. Of those reporting drug use, 18% reported psi experiences during the drug experience, somewhat less than Palmer's 28-29%. Similar to Palmer's work, the use of mind-expanding drugs was positively associated (chi-squared) with OBEs ($p < .01$), and additionally with waking ESP ($p < .05$), apparitions ($p < .01$), and déjà vu experiences ($p < .01$). Except for apparitions, these three experiences tended to correlate significantly with other psi-relevant experiences such as lucid dreaming, meditation, and mystical experiences. None of the studies using Palmer's 46-item questionnaire (Palmer, 1979; Kohr, 1980; Usha, & Pasricha, 1989a, 1989b) made any corrections for multiple inferential analyses, so results should be accepted with some caution.

Returning to the surveys of paranormal belief among students reviewed in the previous section (3.1), these studies also investigated anomalous/paranormal experiences, and Kumar *et al.* (1992) found drug users reported significantly more of these. The later series of five surveys (Gallagher *et al.*, 1994; Houran & Williams, 1998; Pekala *et al.*, 1995a, 1995b; Simmonds & Roe, 2000; Thalbourne, 2001), utilizing the Anomalous Experiences Inventory (Gallagher *et al.*, 1994), each reported a significant positive relationship between the Anomalous/Paranormal Experience and Drug-Use subscales. Correlations ranged from r =.13 (Gallagher *et al.*, 1994) to r =.29 (Thalbourne, 2001), and Pekala *et al.* (1995a) additionally found that drug use was positively correlated with a Shamanic or Encounter-like Experiences subscale (r = .23; $p < .001$), which included items relating to OBE and contact with spirits. Furthermore, Pekala *et al.* (1995b) reported correlations between the use of certain substances and subjective psychic experiences occurring under the influence of drugs, although results were only given for high hypnotically susceptible participants ($n = 56$; for the AEI Drug-Use subscale r =.57, $p < .01$; mind-altering substances r =.34, $p < .01$; marijuana use r =.30, $p < .05$) and high dissociative participants ($n = 59$) (Drug-Use subscale r =.58, $p < .01$; mind-altering substances r =.30, $p < .05$; LSD r =.41, $p < .01$; cocaine r =.34, $p < .01$).

Thalbourne (2001) also found a relationship between drug use and kundalini experiences (r = .28, $p < .01$) measured using the 32-item Kundalini Scale (Thalbourne & Fox, 1999). It was suggested by Thalbourne that the relationship between paranormal experience, drug use, and the kundalini experience either indicates that certain drugs may trigger a kundalini experience or that that the use of drugs may alleviate it. Alternatively, it was proposed that the relationship between these factors may also indicate a need for non-standard sensations, or that the physiological aspects of the kundalini experience were being misinterpreted as paranormal. This final supposition is not consistent with long established tantric teachings that warn of genuine psychic kundalini experiences called "siddhis" (e.g., Satyananda, 1996). Furthermore, as an alternative to Thalbourne's interpretations, the results may simply be due to an overlap of subjective psychic experiences common to both the kundalini and the drug experience, as suggested by Naranjo (1987) and demonstrated by DeGracia (1995) in the following section (3.2.4). Perhaps the activation of the pineal gland and its chemistry, as supposed by Roney-Dougal (e.g., 2001) and Strassman (2001), underlies both factors, resulting in subjective paranormal experiences. Indeed, Roney-Dougal (1989, 1991) noted that the pineal gland is considered by some yogis to be primary in the control of kundalini psi experiences, and there is other putative evidence (see section 1.1) that suggests such a link.

3.2.4 Psychedelic-users samples

DeGracia (1995) conducted a self-selecting internet survey with 61 experienced psychedelic users about their experiences of kundalini-like phenomena. Of those responding, 58% had used psychedelics more than 20 times, most frequently LSD (95%), and psilocybin (82%). The respondents revealed a large overlap between reported psychedelic experiences and those experiences commonly arising in spontaneous kundalini awakenings. Of particular interest, psychedelic drug users frequently reported an enhanced sense of empathy (75%), OBEs (40%), intuition, psychic powers, and the recall of past lives (no statistics given). That the use of psychedelics is related to both paranormal and kundalini experiences is further supported by the survey findings of Thalbourne (2001), as discussed in section 3.2.3.

One of the first surveys (Ditman *et al.*, 1969) to explore paranormal experiences with psychedelics randomly gave 99 alcoholics receiving treatment one of the following three drugs: LSD (the only psychedelic of the three), methylphenidate (a dopaminergic stimulant, also known as Ritalin), or chlordiazepoxide (the first benzodiazepine, a sedative/hypnotic). Those taking LSD reported significantly more of the paranormal-type phenomena, having more experiences of transcending time and of having an OBE supporting findings with the AEI that dopaminergic stimulants (i.e., cocaine) are not conducive to paranormal beliefs.

A survey (Tart, 1970, 1971, 1993) conducted in California in 1970 with 150 experienced users of marijuana recruited by discrete snowball sampling found even higher reports of paranormal experiences than the student and general samples discussed above (section 3.2.3). The marijuana-user sample consisted of 76% students, and 72% of the sample had tried LSD, although only 7% had tried hard narcotics (e.g., presumably heroin). With regard to experiences under the influence of marijuana, 69% reported telepathy (rising to 83% in a later sample), 32% reported precognition, 13% PK (defined as magical operations that cause an effect), and 50% reported seeing auras, with heavier users reporting significantly higher frequencies of these experiences in each category (Tart, 1971). OBEs were reported by 44%, with 53% of this group reporting a least one OBE under the influence (Tart, 1971). In comparison, a later survey (Luke & Kittenis, 2005) found that somewhat smaller percentages of experienced cannabis users (i.e., those using it often or more frequently, $n = 60$) than in Tart's study reported the occurrence of telepathy (20%), precognition (12%), psychokinesis (12%), and auras (22%) while under the influence. Yet, the percentage reporting OBEs either with or without cannabis (62%) was larger than in Tart's study (44%). The use of Californian students at the epicentre of the psychedelic scene at that time may at least partially account for Tart's heightened findings, perhaps because these respondents were more psychedelically active and responsive, and consuming higher quantities and grades of cannabis than in the 2005 survey.

A survey, similar to DeGracia's (1995) investigation of transpersonal drug experiences, was conducted in Sweden with an anonymous snowball sample of 16 experienced psychedelic drug users (Kjellgren & Norlander, 2000). Of those returning questionnaires (94%), 37% had used psychedelics more than 20 times, mostly LSD (75%) and psilocybin (25%). Respondents indicated the occurrence of OBEs (53%), telepathy (60%), the loss of the sense of a discrete self (47%), psycho-geographical traveling (62%), contact with entities (20%), time-travel (40%), animal shapeshifting (53%), and visions of mythological beings (33%), all under the influence of psychedelics. All respondents reported having some psi experiences, with heavier users and, similarly to Usha and Pasricha (1989a, 1989b), those practicing mind-expanding, spiritual, or ritual techniques or preparation reported more of these experiences than infrequent users. However, significant differences in the quantity of experiences between low and high users only occurred for the experiences of telepathy ($U = 12$, $p < .05$, two tailed) and gaining knowledge of oneself, and for a combined index of all paranormal experiences ($U = 7$, $p < .05$), though uncorrected for multiple analyses. This partially supports the hypothesis that subjective paranormal experiences occur more frequently during the use of psychedelics, although alternative explanations are possible. Furthermore, 31% of the sample reported that their views on life after death have been influenced by their use of psychedelics, and 44% had become less afraid of death through their experiences, although 12% had become more afraid.

In further support of the notion that greater psychedelic use is associated with more paranormal experiences, a limited survey of 67 psilocybin-containing mushroom users found that only 9% of those taking low doses (less than 5 dried grams of *Psilocybe cubensis*) had experiences of telepathy, whereas 28% of those taking higher doses - what McKenna (1991) called a heroic dose - had telepathic experiences (Hurst, 1994).

Of particular interest to the present review are the results of an incidental internet survey (White, 1997) of subjective paranormal experiences with the use of the dextromethorphan (DXM). Commonly used in cough remedies DXM is a synthetic drug that results in similar subjective experiences to other dissociatives, such as ketamine and PCP. White was concerned about the use of DXM and had a "frequently asked questions" report regarding DXM posted on an internet-based psychoactive drug information site (www.erowid.org). The published survey, unfortunately without statistics or demographics, was the product of reports sent to White from people who had used DXM, often unwittingly as a simple cough remedy, and had experienced a number of subjective paranormal experiences. White was surprised at the reports and was originally very reluctant to take them seriously, until he received so many that he collated, categorized, and published them.

Many of the experiences reported by White (1997) are consistent with experiences common to ketamine use (Jansen, 2001; Corazza, 2002) and include the following: visions of energy ribbons; a disturbing sense of infinity; a sense of presence of a profoundly powerful, loving, and intelligent being (as is also quoted with DMT use, a very different substance - Strassman, 2001); déjà vu; jamais vu; a loss of sense of causality; memory loops; a sense of presence; OBEs (most often to a different dimension but also on the corporal plane outside of one's body); NDEs; contact with entities, spiritual beings, and other free-floating consciousnesses (also reported by Carpenter, 2006; Xeper, 2005); occasional ESP, including clairvoyance; and the intuitive understanding of complex ideas such as a math student understanding Gödel's Incompleteness Theorem for the first time. Most of these experiences have since elsewhere been reported in an online user journal, *The DXM Zine* (Gelfer, 2007). It is noted there were no reports of PK, although some felt that they could slightly influence the laws of probability. These reported experiences are independently consistent with a psychiatric inpatient report of an apparently accidental overdosing with a cough remedy containing DXM (Price & Lebel, 2000). Reported symptoms included the experience of observing oneself from outside of one's body (OBE), becoming "just thoughts," 360° vision, vision within people, and "delusions" of telepathy, all of which ceased when the DXM wore off.

Taking a more taxonomic approach than earlier research, Luke and Kittenis (2005) sought to determine which of a range of psychedelics are related to which paranormal experiences in particular. The online survey pooled responses from 139 self-selecting respondents recruited via both parapsychology and psychedelic interest groups. The percentage of respondents who had tried an illicit drug even once (n = 110) and who reported a psi experience while under the influence (47%) was somewhat higher than the 28-29% and 18% found previously with general and student samples (Palmer, 1979; Usha & Pasricha, 1989a, 1989b), as might be expected from this non-ordinary sample.

The study also corroborated many of the observations made in previous research. For example, supporting Strassman (2001), DMT was widespread in inducing entity contact experiences and OBEs, although primarily to other dimensions, and like 5-MEO-DMT, DMT commonly gave the experience of dissolving into a universal energy. The hypothesis that DMT is fundamental to the NDE (Strassman, 2001) was partially borne out by the relatively widespread reporting of the, albeit generalized, death-like experiences (dying, rebirth, or memory of a past life) although such experiences seemed to be relatively more widespread with 5-MEODMT, as observed elsewhere (Luke, 2005; RoneyDougal, 2001; Shulgin & Shulgin, 1997).

Reports of "sensing an intelligence or spirit being in an ingested plant or substance" were found to be most widespread where respondents were under the influence of plant-based substances: psilocybin-containing mushrooms, ayahuasca, mescaline-containing cacti, and *Amanita muscaria*, but especially with *Salvia divinorum*, as has been documented elsewhere (Aardvark, 2002; Addy, 2010; Arthur, 2010; Doyle, 2012; Horner, 2012; Miller, 1994; Vayne, 2001). For a discussion of interspecies encounters on psychedelics see Krippner and Luke (2009). Such plant-spirit experiences also occurred with the use of the cannabis plant, although the most widespread experiences with this drug were clairvoyance and OBEs on this plane and, primarily, telepathy, making this substance a prime candidate for ESP research, as has already been advocated by Tart (1993) for a number of reasons. The dissociative DXM is also a potential candidate for further ESP research, particularly collective ESP experiences, supporting earlier reports of psi occurring with its use (Gelfer, 2007; Price & Lebel, 2000; White, 1997). There were also relatively widespread reports of telepathy with LSD and particularly with MDMA, a drug, categorized as an empathogen, that is characterized by its capacity to induce empathic experiences and that has elsewhere been reported to induce telepathic experiences (Brown, 2012a; Eisner, 1989; Saunders, 1993). *Psilocybe* genus mushrooms too demonstrated some relatively widespread capacity to accompany psi experiences of all kinds, particularly clairvoyance, but even PK to some extent. However, possibly because of the more infrequent experience of PK, there did not seem to be any one substance that was related to it, with the possible exception of *Psilocybe* mushrooms, mescaline, and LSD, although none of these convincingly.

In keeping with the previous findings of correlations, ranging from r =.13 to .29, between the occurrence of paranormal experiences (including mystical experiences) and the use of all drugs (excluding prescription drugs) as measured with the AEI (see section 3.2.3), the Luke and Kittenis (2005) study also found a positive correlation of r =.46, p < .001. The greater correlation in this study most likely was due to the use of different sample types, and variations in the questions used. In addition, an overall correlation was calculated between the frequency of paranormal experiences and the frequency of drug use (excluding alcohol and prescription drugs) that gave a small positive value of r =.31, p < .001, supporting Kjellgren and Norlander's (2000) and Tart's (1971) finding that greater psychedelic use is related to more paranormal experiences.

3.3 Surveys and Out-of-Body Experiences (OBEs)

The connection between psychoactive substances and OBEs has received special attention. An inspection of the SPR files led Whiteman (1956) to summarize that approximately a third of "separation" (OBE) cases were initiated by physical conditions, including drugs, although which drugs are not specified. Drug type is clearly of relevance, however, as a study experimentally comparing LSD with Ritalin and benzodiazepine experiences also found that LSD induced a significantly greater degree of OBEs (Ditman *et al*., 1969). Since the 1950s and 1960s several OBE surveys have incorporated questions relating to drug use. Combining two convenience samples of students (n = 192), Blackmore (1982) reported that of the 35 (18%) claiming to have had at least one OBE, 13 (37%) occurred when taking drugs, most often LSD or marijuana. A later questionnaire survey with students (convenience sample, n = 96) found 31% claimed to have had an OBE, and they were significantly more likely than those who did not claim to have had an OBE to have taken drugs such as cannabis, LSD, or opium derivatives (Blackmore & Harris, 1983).

In a similar survey of students from an opportunity sample (n = 200), Myers, Austrin, Grisso, and Nickeson (1983) utilized the OBE question from Palmer's (1979) questionnaire and found a significant, but small, correlation between reported OBEs and the use of mind-expanding drugs (r = .23, p < .001). Similar to the 18% of Blackmore's (1982) study, 22% of the Myers *et al*. sample reported the occurrence of OBEs, with 42% of these having used mind-expanding drugs compared to only 20% using such drugs among those not reporting OBEs. Furthermore, 50% of the OBE experience group (n = 45) reported some psi-related experiences during drug taking, compared to only 4% of the non-OBE group (n = 155), perhaps indicating a commonality in the etiology of drug-induced psi and OBE experiences.

Although these surveys (Blackmore 1982; Blackmore & Harris, 1983; Myers *et al*., 1983) suggest that the use of psychedelic substances is an important correlate of OBEs in the student population, this relationship is less pronounced in other populations. A later randomized postal study (Blackmore, 1984) with a sample of people who had reported OBEs revealed that only 18% of respondents reported OBEs occurring after taking drugs and medicines (type not specified). Blackmore (1992) concluded that hallucinogenic drugs undoubtedly help induce the OBE and were more useful for this than other drugs (e.g., stimulants, tranquillizers, sedatives, and alcohol), although she added that OBEs still occur rarely with psychedelic drug use and there was no specific OBE-inducing drug, despite Lilly's (1978) assertion that ketamine is virtually a chemical road to the OBE. However, Blackmore (2005) later reported an OBE in a self-experiment with ketamine and conceded that, more so than other drugs, ketamine "often involves feelings of body separation" (Blackmore, 2003, p. 356).

The Blackmore OBE surveys (Blackmore 1982, 1984, 1986; Blackmore & Harris, 1983), and that of Myers *et al*. (1983), support the findings of the earlier survey of psychic experiences by Palmer (1979). In Palmer's study, a higher percentage of the student sample than the townspeople sample reported OBEs (S: 25%; T: 14%; p < .01), which Palmer attributed to the likely greater use of mind-expanding drugs among the student sample. Of the townspeople, 7% reported the use of mind-expanding drugs compared to 32% of the student population, although Palmer suspected that the student figure was a gross underestimate, possibly due to the illegality of drug use or the interpretation of the term "mind-expanding drugs" to exclude marijuana. It is not specified why Palmer should consider the student sample to be less likely to report their drug-use than the townspeople. In addition, 13% of the townspeople and 21% of the students reporting OBEs said that at least one OBE had occurred under the influence of such drugs, figures that compare more similarly to the 18% reported for the general OBE population (Blackmore, 1984) than to the 37% and 42% in the student OBE groups (Blackmore, 1982; Myers *et al*., 1983, respectively). In a review of the OBE survey literature, Irwin (1994) agreed with Palmer that the higher reports of OBE experiences among students (20-48% compared to 8-15% in the general population) were probably due in part to students' more frequent experimentation with "psychotropic" drugs. However, Irwin suggested that it was probably also due in part to other factors, such as education and familiarity with surveys.

Using Palmer's (1979) questionnaire, Kohr (1980) failed to find any relationship between OBEs and drug use with the members of the Association for Research and Enlightenment - previous criticisms still standing - although Usha and Pasricha (1989a, 1989b) did find such a relationship with Indian students. The occurrence of OBEs in the Indian sample was positively associated with the use of mind-expanding drugs (chi-squared = 6.87; p < .01) supporting Palmer's findings, although no proportion was given for comparison. Tart (1993) also found that 44% of marijuana users reported OBEs, with 58% of these indicating that their OBE occurred since using marijuana, with 54% of those experiencing OBEs reporting at least one experience whilst actually under the influence of marijuana (Tart, 1971). Most of Tart's sample were also students (72%), supporting Alvarado's (2000) suggestion that the relationship linking psychedelics with OBEs shown in student populations is not evident among the non-student populations, although this assertion is arguably too exclusive of non-student drug-users. For instance, in surveys with psychedelic-users, DeGracia (1995) found that 40% had an OBE while under the influence, and in Kjellgren and Norlander's (2000) sample, of which only 25% were students, OBEs under the influence of psychedelics were reported as 53%, a figure comparable to Tart's marijuana group (54%).

Reports of OBEs are also prevalent in other surveys among users of dextromethorphan (White, 1997). The OBE has also appeared within numerous experiential reports of those who have used either nitrous oxide or ether (Crookall, 1961, 1964; Schroll, 2011), LSD (Eastman, 1962; Grof, 1975, 1980; Lilly, 1969; Whiteman, 1965), PCP (Rudgley, 2000), DMT (Strassman, 2001), 4-HO-MET (Kjellgren & Soussan, 2011), *Salvia divinorum* (González, Riba, Bouso, Gómez-Jaraboa, & Barbanoj, 2006), pituri (Australian Institute of Parapsychological Research, 2004), harmaline and ayahuasca (Andritzky, 1989; Bianchi, 1994; Luna & White, 2000; Naranjo, 1967; Roney-Dougal, 1986, 1989), a host of other plant psychedelics (Schultes & Hofmann, 1992), and even certain simple carbon dioxide and oxygen gas mixtures (Meduna, 1950). That OBEs are also frequently reported to occur with the use of ketamine (Blackmore, 2003; Curran & Morgan, 2000; Jansen, 1997a, 1999, 2001; Lilly, 1978; Muetzelfeldt *et al.*, 2008; Pomarol-Clotet *et al.*, 2006), even apparently veridical ones (Hanna, 2003), is further echoed by a widely distributed UK Department of Health (2004) information booklet, aimed at teenagers, subtitled Facts about Drugs, that states the primary experiential effect of ketamine is an OBE. Furthermore, a taxonomic survey of psychoactive substance use phenomenology found that, out of a possible 17 different transpersonal experiences, OBEs (to another dimension) were the primary experience of both DMT use and ketamine (Luke & Kittenis, 2005). Indeed, a recent online survey (Wilkins, Girard, & Cheyne, 2011) of 192 recreational drug users found that ketamine was the primary predictor of OBEs among a number of so-called recreational drugs (alcohol, cannabis, MDMA, amphetamine, and LSD/hallucinogens), though DMT was not listed specifically. It is also documented that the ancient Indian psychoactive sacramental, Soma, was capable of inducing OBEs (Spess, 2000).

Early OBE researchers were well aware of the occurrence of these experiences with psychoactive drugs and categorized them differently from OBEs with "natural" causes, suggesting that they were of a different type (Eastman, 1962) and of inferior quality (Crookall, 1961, 1972). Blackmore (1986) disagreed, suggesting that a distinction between drug and nondrug experiences was not evident. Similarly, Grosso (1976) stated that both drug and non-drug OBEs have the same characteristics and that the OBE is the extreme manifestation of a normal human process. Grosso further proposed that drug states nicely demonstrated this continuum of out-of-bodyness by exhibiting a range of body-image alterations, from feeling taller to being completely bodiless, offering the most promising means of experimental OBE induction (see section 1.4 for a discussion). Nevertheless at this time, a systemic comparison of the various chemically-induced OBEs and more spontaneous ones is long overdue.

A recent survey substantiates Grosso's (1976) notion by finding that 32% of a sample of 28 first-time users of ayahuasca report alterations in self-body image, ranging from fusion with the environment to the complete separation of the conscious self from the body. All respondents were new members to one of two particular Brazilian syncretic Christian churches that use the jungle decoction ayahuasca as a sacramental (Barbosa, Giglio, & Dalgalarrondo, 2005).

3.4 Summary of Survey Research

In summary, the findings from the survey research indicate a small but consistent relationship (r = .16 to .25) between belief in the anomalous/paranormal and drug use, although the size of this relationship was more pronounced for the marijuana users in Tart's (1993) study. Furthermore, these studies support the hypothesis that psychedelics can induce some paranormal phenomena, although the same arguments for and against the genuineness of field reports (section 2.4) also prevail here. In the surveys reported here, with either student or general samples, those reporting ESP, apparitions, and anomalous/paranormal experiences were found to be significantly more likely to use psychedelics. One study found the same for recurrent spontaneous PK (sometimes called poltergeist phenomena) as well, although only tentatively (Palmer, 1979). Furthermore, of those reporting the use of psychedelics, 18-83% reported psi experiences - most commonly telepathy but also precognition - actually occurring during drug use, with heavier users reporting more experiences where specified. Yet, the occurrence of PK during drug use was only reported among a very small proportion of marijuana, psilocybin, mescaline, and LSD users. OBEs are also an occasional or common feature of psychedelic experiences and are reported to occur with a wide variety of drugs and wide variety of users, particularly students.

A weak relationship between paranormal experiences, the use of psychedelics, and kundalini experiences has also been found in two studies, and there is also a weak, but repeated, correlation between transliminality, drug use, and paranormal experience with Australian psychology students. Where specified, the relationship with paranormal experiences, belief in the paranormal, transliminality, and tolerance of ambiguity is reduced compared to psychedelics with respect to cocaine, heroin, and alcohol, perhaps reflecting Metzner's (2005) classification of these as consciousness-contracting drugs. The same is also true for the negative relationship with the fear of psi found with psychedelics, which is not apparent with heroin and actually reversed with alcohol, although replication and analyses for specific classes of drugs is necessary. Correlations between self-reports of cannabis use and thought transmission in psychiatric research are apparent, often indirectly, though such experiences are also more widely commonly reported in the apparent absence of pathology, with or without cannabis. Many of the surveys fail to adequately identify which substances lead to which experiences, although a switch to such taxonomic research is now evident (Luke & Kittenis, 2005).

4. Experimental ESP Research

Several experiments have attempted to elicit psi directly through the controlled consumption of psychedelics. These experiments have been reported quite differently, sometimes as entire monographs in excess of 100 pages or at other times as footnotes within another published report, often without useful details and statistics. The majority of these experiments were essentially pilot studies and were mostly conducted during the psychedelic research period of the 1960s.

4.1 Forced-Choice Designs

Forced-choice designs are those in which the target is chosen from among just a few known target types, as with the classic Zener cards. Whittesley (1960) reported on the use of LSD (no dose specified) in a forced choice ESP task with 27 participants, using mostly psychiatric outpatients receiving psychotherapy (with LSD presumably). Using ESP cards concealed within opaque envelopes, participants performed two runs of 25 guesses, one before and one after dosing. Neither performance yielded significant deviations from mean chance expectation (MCE), although a chi-squared analysis of the extent of variance revealed a significant reduction in variance ($p < .001$) for scores in the experimental condition. Under the influence of LSD, participants had reported that the card guessing-task was "ridiculous, petty, mundane, etc." (p. 221), and Whittesley suggested such an exceptional lack of deviation from MCE was due to participants feeling so constrained. Little can be said of the methodological merits of this simple experiment because little detail is given, but it is questioned whether the variance analysis was pre-planned.

Making similar use of ESP symbols, Pahnke (1971) reported a pilot study with five participants given a high dose of LSD (200-400 micrograms) and tested 8-9 hours later. The results did not reveal an increase from pre-drug scores for the experimental condition. Pahnke cited the long delay in testing from dosage and, somewhat similarly to Whittesley (1960), the use of an ESP machine with sterile symbols as counterproductive factors. Pahnke proposed that future research would benefit from the use of familiar sender-receiver pairs, with both under the influence, and the use of a stimulant (e.g., caffeine or amphetamine) along with a psychedelic such as 3,4-methylenedioxyamphetamine (MDA) or 2,5-dimethoxy-4-methylamphetamine (abbreviated as DOM, but also known as STP). Despite Pahnke's reported failure, the psychiatrist Grof (1970) reported his own experience taking LSD in one of Pahnke's experiments in which Grof successfully described a remote target in each of three attempts. Grof (1970) aptly described the dissonance between the task and the experience that occurs to the psychedelic participant, a mixture of both complete acceptance and fear of psi, when he wrote:

> When I got the third correct answer in a row, the feelings [of a universe where no laws of time and space exist] were so powerful that I could not continue. The reason for discontinuation of the ESP experiment was a strange mixture of a conviction that it was absurd to test the obvious and, on the other hand, a metaphysical fear of confusion that would follow if I had to give up the usual concept of time and space and with it all the related reference points we feel so secure with. (p. 3)

Prior to using free-response procedures with LSD, Masters and Houston (1966) also experimented with an ESP-card guessing procedure. With each participant performing ten 25-card runs, only 4 out of the sample of

27 participants did better than chance. Those few participants performing better were known very well by the trip guide and had reported a high degree of empathy (with the guide presumably). Masters and Houston noted that participants very quickly became bored with the task and complained that it was "psychedelically immoral" (p. 90) to have them perform card guessing while tripping.

As part of a larger series of individual ESP tests with 36 participants under the influence of psilocybin, Asperen de Boer, Barkema, and Kappers (1966) found that, in ten 25-card runs, no individual scored significantly better than in their own no-drug control condition. The results of the 29,000 ESP-card trials for the 36 psilocybin and 44 control participants (a few participants did multiple conditions) were significantly above chance ($p < .01$) overall. However, a closer inspection of the results showed that, when compared as a group, those in the psilocybin condition scored higher (MCE = .2; mean correct = .214, $p < .05$) than the control condition (mean correct = .206, $p = .09$), although the difference between the groups was not significant. However, there is some indication that order effects reduced any difference between the groups, because the psilocybin condition always occurred after the control condition, possibly resulting in test fatigue, as described in the following section (4.2.1).

Kugel (1977) reported very briefly on the results of a telepathy experiment with LSD, in which test scores actually declined under the influence of LSD in comparison to the periods before and after intoxication. Participants had been given trial by trial feedback and it was noticed that there was a very strong tendency for participants to respond to this feedback by responding with the same call after a hit and a different one after a miss, the latter action being known as the gambler's fallacy. Analysis revealed that this feedback susceptibility increased under the influence of LSD, possibly accounting for the poorer test performance. No further details about the methodology or statistical results were provided in this paper.

In an indirect experiment with participants selected for good psi scoring, Palmer, Tart, and Redington (1976) found a positive correlation between scores on an automated ESP-symbol guessing task in the laboratory and the reported frequency of marijuana use outside of the laboratory, with a negative correlation between ESP scores and alcohol consumption (see Tart, 1993). However, a follow-up study (Tart, Palmer, & Redington, 1979) failed to replicate these results, although Tart (1993) suggested that this was due to the difference in sample groups and the rising popularity of marijuana as a social drug rather than as a tool of self-development. Tart explained this with the observation that the subjective effects of marijuana are highly susceptible to changes in psychological set and expectation, echoing Weil's (1972) suggestion that marijuana is primarily just an active placebo. Nevertheless, direct experimental telepathy research with marijuana by the parapsychologist Dr. Thelma Moss was apparently unsuccessful (Rogo, 1976), though no original research papers on this are readily available. Even so, some similar findings to the original Palmer *et al*. (1976) study were found when scores on a secure non-intentional forced-choice precognition design task with 100 participants (Luke, Delanoy, & Sherwood, 2008) was correlated positively ($r_s = .27$, $p = .008$, two-tailed) with the reported number of consumed psychedelics over the lifetime.

Despite earlier cautions (e.g., Masters & Houston, 1966; Pahnke, 1971; Whittesley, 1960) that ESP-card tests are too boring to those affected by psychedelic drugs, two later studies (Tinoco, 1994; Don, McDonough, Warren, & Moura, 1996) found further support for the forced choice task boredom factor with the use of ayahuasca in Brazil. In a series of 825 ESP-card guessing trials conducted in two 90-minute sessions with one sender and one receiver, both under the influence of ayahuasca, no significant deviation from MCE was found (Tinoco, 1994). A second automated ESP-card precognition test involved one of the previous participants in 625 trials over two separate sessions lasting one hour and 40 minutes each, the scores of which were slightly below chance but not significantly so. However, it is apparent that no control condition was evident for comparison. As in earlier studies, both participants reported that the tasks were boring and that the tests lost their meaning and importance because it was more important to live the visions of the moment.

As part of a larger investigation into EEG variations with ayahuasca use, Don *et al*. (1996) similarly found no significant deviation from MCE with a small group of (presumably experienced) participants using the an automated ESP task under the influence of ayahuasca, though again, like Tinoco's (1994) study, without non-drug controls. Despite the poor preliminary psi-task results, which Don *et al*. attributed to methodological factors, the use of ayahuasca was shown to significantly increase 40-Hz (gamma) activity within the occipital-temporal-parietal area, particularly when the participant's eyes were closed. It was noted that amplification of this kind has often been observed during successful psi-tests in previous studies with gifted participants. Don *et al*. hypothesized that the reported psychic effects of ayahuasca were due to this particular 40-Hz activity amplifying unconscious psi information to conscious levels; however, an independent ayahuasca-EEG study by Stuckey, Lawson, and Luna (2005) failed to replicate the power increases in the gamma frequency range, but instead found increased gamma coherence across the cortex with ayahuasca when compared to control periods.

Unlike most of the other forced choice designs, a series of successful experiments were reported by Puharich (1959, 1962), one of which utilized a 10-image unseen picture-matching test with participants who had ingested the psychedelic mushroom *Amanita muscaria*. Preliminary exploratory work had led Puharich to report the subjective feeling of telepathy himself, and one of his gifted participants perfectly matched two sets of ten unseen pictures in three seconds. Controlled experimental work with 26 unselected participants in independent trials revealed an overall chance occurrence of hits in the control picture matching series (106/1140; MCE = 114) compared to the experimental group (141 hits; $p < .01$), indicating a positive effect of the mushroom on ESP, later repeated in a telepathy-type design.

4.2 Free Response

4.2.1 Psychometry (object reading)

Several experiments have opted for a free-response design, which is arguably more conducive than forced choice in eliciting meaningful responses from participants under the influence, and psychometry has been especially popular. In an exploratory study, using a special sample of six mediums, Osis (1961a) administered 100 or 125 micrograms of LSD to each of them prior to a psychometry test. Five performed at chance whereas one was extremely successful. Although further details were not provided about the successful participant, Osis noted that the others were too absorbed in either the aesthetic pleasure of the experience or the quest for philosophical knowledge. The mediums distinguished the visions from normal perception and stated that the LSD experience was unique and caused a sense of profound unity with the world unlike that occurring during psychic experiences. Osis advised continuing research with drugs where the experiments were brief (only 20 mins.), as longer sessions appeared impractical and were thought to result in negative scores because participants would lose interest. Limited information is provided about this study, although it is assumed that participants were not experienced with psychedelics.

Smythies (1960, 1987) reported a preliminary psychometry investigation - planned more like a remote viewing task - conducted in 1950 with one volunteer using mescaline. Although the participant was unable to discern the targets under adequate blind, remote-viewing style conditions, informal questioning about the target location typical of psychometry tasks elicited promising responses. Similarly using mescaline, a series of pilot studies with three participants "failed in card-guessing tests but showed encouraging success in tests with free material, particularly token objects" (Rush & Cahn, 1958, p. 300), though, unfortunately, further details were not given in this paper. Further to these preliminary reports, Marti-Ibanez (1965) gave a secondhand account of success with mescaline in a series of unpublished telepathy experiments conducted at the Pasteur Institute in Paris. Likewise with mescaline, presumably in self-experiments, Breederveld (1976, 2001) reported success in consistently winning above chance at roulette experiments in casinos using real money, although the mescaline was only one of several mostly successful methods. Nevertheless, Breederveld's success echoes anecdotal reports concerning the pioneer psychedelic researcher, Al Hubbard, who, after apparently developing his psychic ability through the use of LSD (Stevens, 1988), became somewhat notorious for winning on gaming machines in casinos, his reputation being such that he was politely escorted out when he reached a certain limit of earning (Krippner, 2006a).

The most extensive object-reading test of participants under the influence of psychedelics formed part of a battery of ESP tests conducted in a large-scale psilocybin study (Asperen de Boer, Barkema, & Kappers, 1966). In a no-blind repeated-measures design, 44 no-drug control and 36 test participants (30 participants did one of each condition, whereas a few other participants did multiple conditions) given 10 or 20 mg. of psilocybin, were individually tested for four hours for ESP performance with ESP-cards, object reading, traveling clairvoyance, telepathy, and clairvoyance tests regarding both people and objects. Using a complex system for evaluating the success of the free-response tests, the experimenters jointly estimated the degree of probability for each statement given by the participants and then determined the extent to which the probability of correct statements outweighed the number and probability of incorrect statements. All participants were considered to have performed better than chance overall in the object reading, traveling clairvoyance, and clairvoyance-for-persons tests, but those in the psilocybin condition were not considered to have performed better than those in the control condition. However, the free-response results were combined for these three tests so that no separate comparisons between the groups on these tests were reported. Overall performance on the telepathy test revealed 3 hits out of 220 sessions, where 7 were expected by chance, making comparisons between the groups of little relevance, and similarly little success occurred with the clairvoyance-for-objects test.

Asperen de Boer *et al*. (1966) concluded that it is not possible to induce ESP with psilocybin, although Bierman (1998) argued that their participants should be pitied for having to do such a range of boring and strenuous tests while tripping, a burden unlikely to be imposed in modern research. Parker (1975) also criticized the study for promoting a scientific methodology at the expense of interpersonal factors. Furthermore, Asperen de Boer *et al*. made little account for the methodological shortcomings of the psilocybin condition, even though they reported that more than half of the psilocybin participants, mostly drug novices, were distracted by their visions. The authors did note, however, that there may have been some order effects because the psilocybin condition always occurred after the control condition. Of the five participants who completed two control trials, four did worse in the second trial, possibly indicating fatigue effects independently of the drug. Asperen de Boer *et al*. also reported briefly on a previous series of more promising unpublished psychometry trials with LSD that were conducted prior to switching to the psilocybin, which they considered to be less distracting. Out of several LSD participants some exceptionally accurate accounts of object reading where given, for which Kappers (1983) later suggested only a paranormal explanation seemed possible.

4.2.2 Other clairvoyance experiments

Perhaps the first psychedelic ESP experiment was conducted by the French researcher Rouhier who gave mescaline to six subjects, one of whom temporarily developed very detailed and accurate clairvoyant abilities and was able to describe the contents of a nearby room (Rouhier, 1925, 1927). The same sentiment was reported by the man who coined the term *psychedelic*, Humphry Osmond, after his own mescaline experiences in 1951. Osmond (1961) also reported that, in 1957, he and his fellow researcher Duncan Blewett, both under the influence of mescaline, successfully transmitted telepathic information in an informal experiment to such a degree that an independent observer became acutely panicky at the uncanniness of the event, though, unfortunately, no formal experiment with a larger sample is reported.

Using the more popular substances of the 1960s, Cavanna and Servadio (1964) reported extensively on a repeated-measures clairvoyance design with the alternate use of LSD and psilocybin in what was primarily an ideographic, psychoanalytic study. In a series of three control, five psilocybin, and four LSD trials, three participants performed in a single-blind (water placebo) free-response clairvoyance test. In each trial there were 10 targets of combined, yet incongruous, elements (e.g., a foot with an eye), which Parker (1975) unduly criticized for being improbable. Only one participant had a positive attitude towards psi phenomena and all were inexperienced with psychedelics. Participants were given low doses of LSD (40, 50, and 75 micrograms) and psilocybin (10 mg), much criticized by Blewett (1965) for failing to consider the possible dose-dependent nature of psychedelic-induced ESP. Yet despite the low doses and extensive psychological screening one participant had an anxiety attack in the first LSD session, which the authors attributed to demand characteristics expressed through the anxiety and anticipation of the experimenters.

The participants' mentations were rated for correspondences by three experimenters and then independently by two blind judges, with reasonable correspondence between the judging groups, though Blewett (1965) argued otherwise. Compared to the control conditions, the blind judges' results with both the LSD and psilocybin showed a clear improvement in ESP ability, with some accurate correspondence with about one in five of the targets for both drugs. Notably, no success at all was achieved in the three control conditions, though unfortunately no estimation of the probability of the results was given, nor were inferential statistical analyses possible because the design had no decoy targets in the judging process, as duly criticized by Smythies (1965). Although the results are positive, caution is raised concerning any inferences drawn from so few trials. Cavanna and Servadio (1964) suggested that further research should make use of: stronger emotional targets, greater emphasis on interpersonal relations, and use of free association rather than interview.

A study of some indirect relevance investigated the effects of low-dose LSD (65 micrograms) on apparent subliminal perception with five participants (Freidman & Fisher, 1960). Participants were shown a bold image faded out below the subjective threshold of (conscious) discrimination with several layers of paper and presented after a blank control image in repeated trials. Analysis of free-response descriptions of the hidden image by independent judges revealed that participants gave significantly more accurate descriptions of the target in the experimental condition under the influence of LSD compared to the control condition, and that these participants also performed significantly better with LSD in the experimental condition than they had done six weeks previously without LSD. The results were interpreted as indicating the enhancement of subliminal perception with LSD; however, they might also be due, partly or wholly, to the enhancement of ESP with LSD. This is because the design mimics an ESP-study design in protocol, and there is some evidence to suggest that ESP is an active factor in subliminal perception research (Stanford, 1990). Alternatively the results may be due to poor methodology, such as order effects, quasi-experimental design, and expectation or other bias due to the lack of blind controls across all conditions and the repeated use of the same subliminal target image. Furthermore, according to Cheesman and Merikle (1986), the mere perception of information from between the subjective and objective threshold, as in this study, is not strictly subliminal perception, but unconscious perception.

Based upon earlier recommendations to avoid boring and repetitive test procedures with participants under the influence of psychedelics, a series of pilot ganzfeld experiments with cannabis (marijuana) and psilocybin were conducted (Wezelman & Bierman, 1997; Bierman, 1998). In the first series, Wezelman and Bierman utilized a no-sender auto-ganzfeld setup with 40 participants pre-selected for experience with marijuana. In a randomized crossover design, participants performed two trials each, one self-dosing marijuana condition and a control condition. All but four participants, who became nauseous and dropped out after the first session, completed both trials. A planned mixture of subject judging or external judging was used. The control condition had a hit rate of 15% (MCE = 25%) compared to 30% for the marijuana condition, and Bierman (1998) noted that the score for the marijuana condition was mainly due to the external judges, particularly one experimenter-judge who was also using marijuana. However, scores for the experimental group were not significantly different from MCE.

Wezelman and Bierman (1997) also reported on findings from a no-sender ganzfeld pilot-study conducted with six psilocybin-experienced participants performing two trials each under the influence of psilocybin. There was no control condition. Utilizing a buddy system to deter bad trips, pairs of receivers performed the ganzfeld together. With only subject judging this time, participants in the psilocybin group scored 7 direct hits out of 12 trials (58%), a figure that even with only a few trials is significantly deviant from MCE ($p < .05$), although uncorrected for a stacking effect (see Milton & Wiseman, 1997, p. 93).

4.2.3 Telepathy experiments

Bierman (1998) continued with the previous work, this time in a telepathy design using a within-subjects control condition with 20 psilocybin-experienced participants who each performed one control and one psilocybin ganzfeld trial with a sober sender. Participants in the psilocybin condition scored at chance (25%), whereas in the control condition they performed slightly below (20%), with no significant difference between the two. However, a post hoc analysis of the results for negative and positive clips revealed an interaction between target emotionality and drug state, with a much higher hit rate for positive clips (44%) than negative clips (8%) in the psilocybin condition and a reversal of this effect in the control condition. This interaction was explained in terms of psilocybin participants possibly detecting the positive ESP targets, but blocking the negative images to deter bad trips, given that participants were tripping alone this time; however, the reverse effects for the control condition are not as easily explicable. Bierman interpreted this result as suggesting that psychoactive drugs affect psi performance and that target emotionality and the psychological set of the participant may interact to alter the results. It is also worth noting that ganzfeld experiments with psychoactive drugs are likely to induce a unique, possibly combined, state of consciousness, unlike the usual drug or ganzfeld experience alone, given that the ganzfeld environment is considered by many scholars to already induce a unique kind of ASC (e.g., Wackerman *et al*., 2000). However, this idea needs further verification.

Coming from the field of psychedelic experimentation rather than parapsychology, towards which they reported being skeptical, Masters and Houston (1966) conducted a series of ESP experiments in which they demonstrated a much greater degree than their contemporaries of familiarity with the effects of the drugs being used. They provided an experienced trip guide, with whom most participants were familiar, and utilized experienced trippers as participants. The study had 62 receivers, with their guide as the sender of the 10 static image targets, and only the receiver under the influence of LSD. Using independent judges, the majority of the 62 receivers (77%) gave free-recall responses approximating the target at least 2/10 times, with five of these participants approximating the target image 7/10 or 8/10 times. The remaining 14 participants (23%), who performed worse, were either unknown to the guide, anxious, or primarily interested in their own personal psychological narrative rather than the ESP task, though these observations may be post hoc. Sometimes, receiver statements also matched non-target thoughts of the sender. But Parker (1975) noted that non-verbal communication from the guide could not be ruled out. Once again, no estimation of the probability of describing the target image is known, because no decoy images were used in the judging process and no comparison was made to a control condition to establish if LSD actually improved scores. Nevertheless, accuracy rates were similar to those reported in the clairvoyance procedure of the same nature by Cavanna and Servadio (1964), where LSD and psilocybin scores exceeded those in control conditions. Cavanna and Servadio further reported an exploratory sender-receiver telepathy design with one LSD trial and one control, where only the receiver took LSD. The results indicated accurate comparisons in approximately one in three of the targets for LSD, with a rate of only one in ten for the no-drug control condition.

Following up from a previous forced-choice ayahuasca ESP study (Tinoco, 1994), Tinoco (2011) conducted a free response task in 1995 with three participants under the influence of ayahuasca acting as senders and receivers in a telepathy-type task. No use of decoy targets was made in the judging procedure, nevertheless three independent judges concluded that there was no correlation between the target and the response in any of the 15 trials; however, no exact probability of getting a hit can be calculated with this method, and the interpretations of the judges are subjective. Furthermore, no control group was used for comparison, it is not clear how the targets for sending were initially chosen, and participants complained that they were not getting any visual imagery and, as with the two previous ayahuasca studies, that the task was boring in such a state.

Finally, Puharich (1962) followed up his earlier success at clairvoyance with *Amanita muscaria* with a demonstration for four Los Angeles news reporters, who also acted as participants and who were either skeptical or hostile towards the idea of drug-induced psi. The design relied on a computer-recorded random number-series guessing task with a non-drugged sender elsewhere, though where was not specified so sensory leakage cannot be ruled out. Participants scored at chance in the control condition (35 hits in 297 trials, nonsignificant) and after ingestion of *A. muscaria* repeated the test (average 40 mins. later) and made a combined score of 65 hits in 432 trials ($p < .005$). Scoring returned to chance after two and half hours, as they had in the previous clairvoyance experiment, although participants still reported feeling that their intuition was active. Puharich (1962) attributed the results to the neurochemical action of cholinergia heightening the ESP function by activating the parasympathetic functions (slow heart rate, etc.) indicative of the trance state. However, this explanation is somewhat erroneous because the psychoactive principles in *A. muscaria* - muscimol and ibotenic acid - can both calm and stimulate the central nervous system, respectively, whereas the cholinergic chemical, muscarine, is now known to be only a trace and psychologically inactive constituent of the mushroom (Michelot & Melendez-Howell, 2003). There is also the possibility that optional stopping occurred in this latter experiment as indicated by the different number of trials in the control and experimental conditions, and Krippner (2006a) also raised concern that Puharich's research, as with Masters and Houston (1966), was reported in a self-authored book rather than a peer-reviewed journal.

4.3 Summary of Experimental Research

Due to the exploratory nature of most of these experiments, it is difficult to fully assess their efficacy using psychedelics to produce ESP (no PK experiments having been attempted). In most cases this could have largely been improved with an adequate control condition without order effects (Palmer, 1978), and the blind use of decoy targets in the judging process. Procedures using subjective probability estimates by experimenters (such as Asperen de Boer *et al.*, 1966) are now virtually obsolete in parapsychology because they are so difficult to assess and are prone to bias (Parker, 1975). In the one ESP-card experiment to use a control condition, scores in the psilocybin condition were significantly different from chance and were also superior to the control condition, although not significantly (Asperen de Boer *et al*., 1966). Nevertheless, it is apparent that those experiments using ESP-card type symbol guessing procedures were largely unsuccessful compared to chance expectation.

The use of the symbol-guessing procedure has been widely criticized for being far too mundane under the influence of psychedelics (Grof, 1980; Masters & Houston, 1966; Pahnke, 1971; Parker, 1975; Rogo, 1976; Stafford & Golightly, 1967; Smythies, 1960; Tart, 1968; Whittlesey, 1960). Even so, using *Amanita muscaria*, Puharich (1962) demonstrated that forced-choice procedures could be successful with picture-sorting tasks. More engaging, free-response procedures have demonstrated at least some success in all but one of the studies that have used psychometry, although rarely with any control condition for comparison. A clearer indication of possible psychedelic-induced ESP, even at times in comparison to a control condition, comes overall from the clairvoyance and telepathy designs, except for the Asperen de Boer *et al*. (1964), Tinoco (2011), and the marijuana ganzfeld studies (Wezelman & Bierman, 1997). Replication, however, is needed and, in some cases, with better methodology and preplanned analyses. It remains curious that no formal explicit experiments with precognition or PK have been performed, particularly the former because powers of divination are traditionally attributed to many plant psychedelics.

5. Methodological Critique of Experimental Research

When consideration is given to what has been learned from these largely pilot studies, experimenters and commentators alike have highlighted the difficulties involved in attempting to test for psi with participants who have taken a psychedelic. Aspirin de Boer *et al*. (1964) suggested that the participant's willingness to perform in the task was important, but given that participants have difficulty maintaining alertness, self-control, focus, interest, and orientation to the task (Edge, Morris, Palmer, & Rush, 1986; Millay, 2001; Rogo, 1976), it seems much more important to consider the participant's "capability" to perform in the experiment rather than their mere willingness. Parker (1975) notes that a participant's increased sensitivity to subtle influences under psychedelics is both a boon and a bane to research. Indeed, using psychedelics to induce psi is a double-edged sword, namely all of the reasons cited in the introduction that make such research alluring also make participants poor test subjects. This is because participants may become engrossed in the experience (Rogo, 1982), the aesthetic rapture (Osis, 1961a; Smythies, 1960), the quest for philosophical knowledge (Osis, 1961a), a deep soul-searching self-examination (Blewett, 1963), one's own personal drama (Millay, 2001; Parker, 1975), and the flow of thoughts (Ryzl, 1968). In addition, participants may have difficulty communicating because of the lack of adequate language (Lilly, 1969), the overwhelming flood of ideas and emotions (Ryzl, 1968) and the speed of change of the internal experience (Blewett, 1961b, 1963). The experience of dissociation (e.g., with ketamine) can also hinder communication when participants become no longer present or aware of their physical environment and, as Huxley (1961b) pointed out, there is a need to assure participants of their identity once constructs of space and time disappear. Blewett (1961a) further warned of other unwanted psychological reactions that may occur if participants attempt to either escape from or rationalize their experience.

However, it is apparent that these obstacles to research may be greatly alleviated or even eliminated if participants are experienced with the use of psychedelics (Blewett, 1963; Parker, 1975; Tart, 1977). Indeed, about a quarter of inexperienced participants are expected to have intense spontaneous mystical experiences during their first trip (Wulff, 1997, 2000). Yet, very few of the studies reviewed here (only Bierman, 1998; Masters & Houston, 1966; Wezelman & Bierman, 1997) specifically reported the use of participants experienced with these psychedelics, although it is worth noting that those that did were relatively more successful than those that used inexperienced participants. Further to this, it has been suggested that experienced psychedelic participants can be better trained to stabilize their experience (Millay, 2001; Tart, 1977) and may even naturally train themselves to stabilize experiences through repeated use (Levine, 1968). Regardless of training, it has been strongly advised that participants be allowed to stabilize their experience before testing begins (Blewett, 1963, 1965; Millay, 2001; Parker, 1975; Tart, 1977). Pahnke (1968) further recommended an 8- to 12-hour pre-dose preparation period when working with terminal cancer patients, although Ludwig (in Tart, 1968) questioned the necessity of this in a parapsychological context.

Stabilization of the experience may even be expedited by inducing hypnosis prior to drug administration (Parker, 1975; Tart, 1968) in what has been called the "hypnodelic" state (e.g., see Levine & Ludwig, 1965;

Ludwig 1968; Tart, 1967). Alternatively, Ryzl (1968) reported re-inducing LSD states through hypnosis, as is also reported elsewhere, although it was uncertain how successful this was (Ludwig, 1968), though success inducing other drug states (e.g., MDMA, heroin) has also been reported (Hastings, 2006; Hastings *et al*., 2000; Ludwig & Lyle, 1964). Similarly, Farber (2000) has described the successful re-induction of psychedelic states using hypnotic anchoring techniques available in neuro-linguistic programming. Perhaps, the entire psychedelic experience can be stabilized and anchored during test trips with experienced users and then later re-induced, with or without hypnosis, so that no psychedelics are actually taken during the test procedure. Testing for psi under such "controlled flashbacks" may overcome most of the stipulated problems, and have the added advantage of investigating Rogo's (1976) question of whether it is the neurochemical action of the drugs or the state induced that can seemingly produce psi.

Although some researchers (Halliday, 1961; Nicol & Nicol, 1961; Paterson, 1961a; Smythies 1960; Tart in Levine, 1968) suggest that using good psi scorers, psychics, and mediums in drug studies would improve scoring, Eileen Garrett (1961b) noted that although LSD enhanced her mediumistic experience it would not improve forced choice test-scores. Echoing this, the Osis (1961a) experiment has shown that using mediums did not prove any more successful than the use of normal participants in the other psychometry experiments. This was probably due to all the problems mentioned already that occur more with inexperienced psychedelic users, indicating that sample selection should primarily seek to select experienced users over psi-effective participants, although, presumably, ideal participants would be both, though not necessarily.

Considering aspects of timing, several authors have offered advice, though no formal studies have been conducted. Both Ryzl (1968) and Grof (1980) suggested that the optimum period for testing psi during the LSD session was towards the end when the effects were leveling off, as in the Masters and Houston (1966) experiments, yet Pahnke (1971) disagreed. From extensive personal experience, Copley (1962) suggested testing for ESP once the trip had finished. As regards to the duration of the psi-task, rather than the extended test periods favored by some researchers (e.g., Asperen de Boer *et al*., 1964; Tinoco, 1995), Osis (1961a) suggested 20 minutes should be the maximum for optimum performance.

Some consideration has also been given to the optimal substance. Pahnke (1971) recommended combining stimulants with psychedelics, whereas Asperen de Boer *et al*. (1966) chose psilocybin over LSD, due to it being milder, with which Cavanna and Servadio (1964) agreed. Indeed, LSD has a much longer duration of action than psilocybin and as Blewett (1963) noted, 10-hour trips are hard to staff. Ryzl (1968) also questioned the utility of LSD in psychedelic psi testing and proposed that the ideal substance, if it can be synthesized, should inhibit cortical activity to suppress the stream of thoughts, depress sub-cortical activity to block incoming stimuli and excite spheres of the cortex involved in ESP production, yet maintain rational insight, and increase suggestibility. However, such a designer drug is far in the future, though such psychochemical engineering may one day be possible (Brown, 2012b); moreover, there are an increasing number of ethnobotanical substances becoming known that have traditionally been used for psychic purposes, which have not yet been thoroughly tested, or even tested at all (e.g., *Salvia divinorum*).

Tart (1993) further suggested that marijuana was an ideal substance for psi experimentation because of its wide familiarity within the public, its mild psychedelic qualities and its reputed ability to induce psi, experientially at least. Puharich's (1962) apparent repeated success with *Amanita muscaria* also needs replicating. Furthermore, other non-psychedelic chemical psi research, such as de Pablos' (2002) unsuccessful first-person precognitive-dream drug-study, could also be replicated with the use of psychedelic substances that have actually been reported to induce psi in dreams. For instance, there are reports of precognitive dreams, by both traditional users and by modern consciousness researchers, with substances such as *Calea zacatechichi* (Devereaux, 1997; Díaz 1979; Mayagoitia, Díaz, & Contreras, 1986), *Silene capensis* (Hirst, 2000, 2005; Sobiecki, 2008, 2012), and tree datura (*Brugmansia*; Metzner, 1992; Schultes & Hofmann, 1992). Other substances seem best suited to other experimental designs too, for example, telepathy-like experiments might also benefit from the empathogenic effect of substances like MDMA, as the one participant under its influence in a remote detection experiment did exceedingly well (Brown, 2012a). The use of a placebo in a double-blind or blind control condition, as in Cavanna and Servadio (1964), is of questionable utility in this type of experiment because at anything less than sub-threshold doses the participant is likely to easily detect the effects of the drug; nevertheless, researchers should be aware that placebo drug effects have been demonstrated in ESP research when coupled with positive false feedback on task performance (Pitman & Owens, 2004).

Several researchers have also commented on the importance of dosage (e.g., Braud, 2002; Levine, 1968). Blewett (1961b) warned that giving participants low doses of LSD may not be sufficient to break through the barrier between the normal and the full-blown psychedelic state and can be merely disorientating rather than transformative, and he later suggested that doses up to 1,500 micrograms of LSD (a very large dose) need investigating, because ESP might be dose dependent (Blewett, 1965). Support for this logic is also evident in escalating dose research with DMT (Strassman, 2001). It is additionally advised that experienced participants control their own dosage (Tart, 1977), as in the experiment by Wezelman and Bierman (1997). Participant's self-reports of the depth of the altered state were also considered better than dosages as indicators of subjective effects (Tart, 1977). Self reports using the Hallucinogenic Rating Scale were also considered better indicators of dosage than physiological measures (Strassman, Qualls, Uhlenhuth, & Kellner, 1994), though the use of a scale of transpersonal experience, such as the Self-Expansiveness Level Form (Friedman, 1983; Pappas & Friedman, 2007), would also likely be fruitful in discerning the relevant depth of the psychedelic ASC. Furthermore, some researchers (e.g., Parker, 1975; Tart 1968, 1977) have noted that the issue of dosage is largely irrelevant in comparison to the influence of the psychological factors of set and setting, as originally noted in psychedelic research by Leary, Litwin, and Metzner (1963). In discussion of this, Vayne (2001) suggested that the influence of psychological factors on psychoactive drugs can vary their effects so much that the drug can be thought of primarily as an experience, composed of set, setting, and substance.

Factors considered important in determining psychological set include the participants' expectations, attitudes towards themselves, idiosyncratic perceptions, and emotional orientation to the experiment (Levine, 1968; Tart, 1968). It is also deemed imperative to engender a sense of self-surrender, acceptance, and trust (Blewett, 1963). Factors considered important in determining psychological setting include those that are ordinarily considered under demand characteristics (Parker, 1975; Tart, 1968, 1977), particularly the experimenter's attitude, which should be warm, friendly, and supportive (Blewett, 1963). Psychological issues induced through interpersonal relations within the laboratory become magnified when participants are on psychedelics (Blewett, 1963; Parker, 1975). Cavanna and Servadio (1964) highlighted this when one of their participants had an anxiety attack concurrent with their own anxiety, which led them to advise that the experimenters themselves should be experienced users of the psychedelic substance under investigation, as also advised by Strassman (2001). Tart (1968) also recommended that the experimenter should guide the experience towards the goal of the study, and has criticized previous work for assuming psychedelic states automatically induce psi, because, as noted by Tart, Osmond, and Beloff (in Levine, 1968), and Puharich (1959), in traditional scenarios the shamans who use these substances usually have extensive training and experience. It is further suggested that the experimental task be shaped to the state of the participant, not vice versa (Tart, 1977), and utilize the strong motivation, directed awareness, and complex ritual that is found in shamanism (Copley, 1962; Grof, 1980; Tart, 1968). Grob and Harman (1995) have also urged the integration of aspects from shamanic practices into scientific procedure so that there is attentiveness to factors of set and setting, such as intention, expectation, preparation, group identification, and formalized structure, as well as the integration of the experience in the following months. Indeed a multi-method approach to studying psychedelic shamanic practices is advised, so that ethnography can inform suitable experimentation (Giesler, 1984, 1985; Luke, 2010a). Nevertheless, Storm and Rock (2011) pointed out that, in psi research with psychedelics, researchers need to be aware of the difference between shamanic techniques and merely shamanic-like techniques; for example, the latter may lack the purpose of serving one's community. Furthermore, Tart (1977) has recommended the implementation of mutual research, where participants are considered as coinvestigators, to reduce experimenter bias and enhance a sense of participation, trust, and motivation.

6. General Summary and Conclusions

Even though the subjective paranormal experiences, clinical observations and anthropological reports are subject to all the usual criticisms and rebuttals that apply to non-experimental cases (e.g., see Stokes, 1997) there is a growing body of reports, rooted in thousands of years of traditional psychedelic use, that supports the notion that genuine paranormal phenomena do occur. Nevertheless, as evidence this data is not scientifically rigorous, yet it has great value in mapping the phenomenological terrain of paranormal experiences with psychedelics. This body of reports is further supported by correlations from surveys linking psychedelic use with the increased reporting of paranormal experiences and belief in the paranormal, although again, self-reports have more phenomenological merit than evidential value. Furthermore, even though it can be considered little more than exploratory at this stage, the experimental evidence is more positive than not and proves promising so far, illuminating both methodological pitfalls and possibilities.

It is apparent that parapsychopharmacology is a multidisciplinary endeavor pooling expertise from anthropology, ethnobotany, phytochemistry, neurobiology, psychopharmacology, psychiatry, psychotherapy, transpersonal psychology, and indeed parapsychology. It also owes much to the non-academic explorers of consciousness, be they shamans, occultists, or psychonauts. It is a branch of research that is still very much in its infancy, and, along with other fields conducting research with the use of psychedelics, has been operating very quietly since the late sixties until a gentle turn in the tide during the last decade or so has seen experimental research resumed (see Grob & Harman, 1995). Nevertheless, further experimental research continues to need strict ethical and often governmental approval before it can proceed, requiring lengthy applications (see McKenna, 2004; Strassman, 2001). Several years ago, Tart (1977) recommended bypassing these difficulties by casually enrolling participants who were already using psychedelics, rather than having the experimenter administering the substances directly. An example of this kind of experiment involved several thousand Grateful Dead fans, renowned for their psychedelic consumption, who acted as senders in a series of dream telepathy experiments with some success (Krippner, 1999; Krippner, Honorton, & Ullman, 1973; Roberts, 2004). Indeed, taking what Giesler (1984, 1985) calls a psi-in-process approach and keeping naturalistic variables intact, group experiments may be one way to access the kind of group telepathy experiences that people tripping in groups sometimes report (e.g., Grey, 2007; Nuttal, 1970; Stevens, 1989; Wolfe, 1971), especially on DXM (Luke & Kittenis, 2005). However, without the grounded and controlled atmosphere of a concert or shamanic ceremony, psychedelic group ESP experiments run the risk of turning into bacchanalian scenes, as once witnessed by Puharich's wife (Hermans, 1998).

However, now resumed, direct parapsychological research with psychedelics needs expanding beyond the Netherlands and Brazil - the only place where experimental psi-chedelic research has been conducted since the 1970s - and treating these substances like any other drug worthy of investigation within a medical or therapeutic context has recently proven a fruitful means of inquiry for many researchers (Doblin, 2004; Grob & Harman, 1995), although psi research does not readily attract such funding at the present time. Nevertheless, it should be noted that psychedelics are considered as sacramentals by the spiritual and religious groups that use them and they must be utilized and researched with respect. It is also clear that besides trying to replicate the promising free-response studies, further experimental psychedelic research should utilize protocols that maximize psi effects, and this work can then simultaneously enhance process research methodology by indicating optimal conditions for psi through the psychologically magnifying effects of these substances. For instance, Bierman's (1998) psychedelic psi research may have revealed the apparent psychic blocking of negative images, and, from earlier experiments, forced-choice tasks are clearly too mundane. Research should also seek to study these substances in the shamanic context in which they have most effectively been used, designing appropriate test protocols for traditional settings. A recent example of which is Hirukawa *et al.*'s (2006) apparently successful demonstration of psi using a field random event generator in an ayahuasca ritual with the Santo Daime church in Brazil.

Additionally, following in the footsteps of William James, there has already been some return to self-experimentation with psychoactive drugs by de Pablos (2002, 2004), who has developed a viable protocol for testing one's own precognitive dreaming abilities with drugs, which might easily be adapted to waking experimentation as well. All experimental research should also be designed and conducted with an appreciative consideration of Tart's proposals for the creation of state-specific sciences (Tart, 1972, 1998, 2000, 2001). In the future, parapsychologists might ask their participants about their drug use, and researchers investigating the use of psychedelics might once more include questions relating to paranormal experiences (e.g., Echenhofer, 2005). Furthermore, with an ever growing number of substances being discovered and a large natural data pool of psychedelic users, there is a need for more thorough and focused phenomenological research that investigates and identifies the types of paranormal experience that occur through the use of each of these diverse psychedelic substances (Luke, 2004a, 2004b, 2004c; Luke & Kittenis, 2005).

Finally, there is much that can be offered to transpersonal studies from the investigation of parapsychopharmacology, and vice versa. Certainly it is clear that no study of the extraordinary phenomena of the psychedelic state would be complete without the insights and perspective of transpersonal psychology. Indeed, many of the exceptional experiences encountered with psychedelics involve parapsychological elements and yet they also go beyond the ordinary scope of parapsychology into the wider transpersonal realms (Luke, 2012b), such as entity encounters (e.g., Luke, 2011b) and profound mystical experiences (Luke & Kittenis, 2005). It is also somewhat inevitable then that this course of research is as likely to culminate in transformation for the researcher as it is in evidence for the genuine existence or otherwise of psychedelically induced paranormal phenomena (Luke, 2011c). It is also illuminating at this point to consider this research in terms of Tart's (2002) evaluation of these related fields of enquiry, where parapsychology is to transpersonal psychology what physics is to engineering: One researches the fundamental technical nature of the subject matter so that the other may apply it. In the current case a great deal can be learned, as Tart reminds, about the fundamental nature of mind through the study of parapsychology and - by looking to the psychedelic dimension - about the neurochemical mediation of exceptional aspects of consciousness in particular. Ultimately, however, it is down to transpersonal psychologists how they use this knowledge and apply it, though, fortunately, the history here tells us that wisdom usually prevails.

Acknowledgements

This research was initially supported by a grant from the Multidisciplinary Association for Psychedelic Studies (www.maps.org). The author would like to thank Stanley Krippner, Marios Kittenis, Debra Weiner, Nicola Holt, Harris Friedman, and Adam Rock for their help in the preparation of this manuscript. Earlier drafts of parts of this manuscript appeared in Luke (2008b) and Luke and Friedman (2010).

The Influence of Psychedelics on Remote Viewing

by

Jean Millay, Ph.D

(A more complete discussion of this topic can be found in Multidimensional Mind: Remote Viewing in Hyperspace, by Jean Millay, Ph.D., with a forward by Stanley Krippner, Ph.D.)

original source: http://www.maps.org/news-letters/v11n1/pdf/11143mil.pdf
backup source: http://www.psilosophy.info/resources/11143mil.pdf

> In 1997, students at the University of Amsterdam in the Netherlands did research to establish whether or not the use of psychedelic substances could influence remote viewing. In this report, the test-subjects who were under the influence of cannabis chose the right target at an average rate that was only slightly above chance expectancy. Those who were under the influence of psilocybin achieved a rate of success of 58.3%, which was statistically significant. This was a small experiment with only 12 test-subjects.

The process of doing remote viewing, with or without psychedelics, requires an ability to focus attention and to be able to clear away any personal and/or emotional issues that would interfere with perception of external images and cause them to be skewed. I never use the term "extra-sensory perception" or "ESP" because it implies that there is an EXTRA sense somewhere that accounts for telepathy. This is counter-productive in attempting to understand how psi phenomena works. All our senses can be extended for use and interpretation of incoming information. One of the uses of psilocybin is that it can contribute to the extension of one's ability to focus attention very precisely on something or some problem until it is understood at a higher level. Another of the many uses of psilocybin is that it facilitates one's ability to access non-local spacetime (the hyperspace) which is where remote viewing can be done. Cannabis can be utilized in this manner, as well. However, the quality of the cannabis is important, and one needs to practice with it, to know and understand just how the process of remote viewing works best. It is also important to remember that the inexperienced users of psychedelics can find themselves in the middle of a major cosmic drama, and if so, this must be resolved first and foremost. No remote viewing should be attempted during such a session that is essential for the clearing of preconscious material. In my informal studies beginning nearly forty years ago, I have used LSD, mescaline, or psilocybin, if I had an urgent need to communicate with someone at a distance, when a telephone was not available. Each of these substances worked fairly well under such needy conditions. At other times, my colleagues and I would use one of these substances to try sending and receiving simple messages just to explore and to study the potentials of this direct mind-to-mind communication process. When we compared our responses afterward, we discovered how our memories and internal dialog could skew the results. After a time, I began to realize that what we learned about the process was now part of what we could use at any time. We no longer needed the boost that the strong psychedelics, mentioned above, provided. It was at that time, that I learned that cannabis could be used just as well And even when that was not available, I could focus my attention with my own intention set to do so.

Later, I conducted a formal study for my Ph.D. dissertation with college students who formed eleven telepathic teams. These were couples (lovers or friends since childhood) who volunteered because they wanted to learn to improve their own communication with each other. In this first study we did not use psychedelics or cannabis. We used biofeedback to train the volunteers to synchronize their alpha brainwaves between right and left hemispheres, and later with each other. One semester was not enough time for some of the couples to learn EEG synch and some did not receive telepathic messages any better than chance. However, when all scores were counted at the end of the experiment, we found that those teams who had the best scores in paired EEG phase coherence were also those who had the best (better than chance) average scores in blind match telepathy. This trend was continued in a later study as well. (Both studies were statistically significant at $p < 0.001$.) It is important to notice that the brainwaves were not measured at the same time that the telepathy was tested. In one case, the electrodes interfered with concentration for telepathy, and in the other, the attempts to communicate telepathically interfered with the intent to synchronize brainwaves. So we cannot say that one is the "cause" of the other, but that both are related to the ability to focus attention in a precise way. (For details, see my book, Multidimensional Mind: Remote Viewing in Hyperspace, available at Amazon.com).

In the late 1970's, we conducted another study designed to examine the possible effects that smoking cannabis had on the EEG of volunteers. In this study we used the same equipment as we had used in the previous study (i.e., two Aquarius Electronics brainwave biofeedback analyzers with the phase comparator, designed by Tim Scully, Ph.D.). A good grade of cannabis was obtained so that each volunteer would be smoking the same material. In those days, the EEG biofeedback equipment was often used to judge the quality of mind-altering materials. If a person lost some voluntary control of his/her brainwaves (that she/he had previously learned) by using any substance, it was felt to be inferior. (Obviously, if that material was used too often, one would lose some aspect of thought, eventually.) If a person gained some ability to exert voluntary control over his/her brainwaves by using some substance, then that material had the potential of being "mind-expanding." This was the rule of thumb, at that time, and occasionally students at "Altered State College" would request the use of our equipment to test their own material.

Because of the intense interest in that community in the actual effects of cannabis, volunteers requested that we do such a study since we had the equipment available. We began by establishing the base line of EEG frequency range for each individual. Then with biofeedback, we also recorded the initial alpha phase-coherent scores for each one, and for each team. Then we introduced a good grade of cannabis for each one to smoke, and took the EEG phase-coherent scores again at intervals. In each case, all volunteers recorded a dramatic increase in their individual interhemispheric alpha phase-coherent scores. However, some of the couples showed an increase in their interpersonal alpha phase-coherent scores and some couples showed a decrease from their baseline scores. Those couples, whose interpersonal alpha phase-coherent scores increased after smoking, described their experiences as being totally focused on each other, especially on touch. Those couples, whose interpersonal alpha phase-coherent scores had decreased after smoking, reported that they had "spaced out," that is they no longer focused on each other but enjoyed thinking about separate events, or creative ideas. (Their interhemispheric synch scores remained high, but their interpersonal synch scores decreased.)

One suggestion here is: since brainwave biofeedback can help people to increase their ability to increase alpha phase-coherence (along with their ability to focus attention), and if the ability to focus attention is relevant to increased accuracy in telepathy, then when one can learn to increase alpha phase-coherence with the use of a good quality of cannabis, a research study might very well be able to find that cannabis can increase the ability to do successful telepathy among those couples who already have established some rapport. We must remember, however, that clarity of mind is always a consistent requirement.

Additional research in this area needs to be done by those who can focus attention on the real issues of the multidimensional realms available to each of us. With or without psychedelics, telepathy and remote viewing are possible. Psychedelics have introduced millions of us to the concept of non-local spacetime and have opened the "doors of perception". The doors cannot be closed again!

Sacred mushrooms inspire medical research

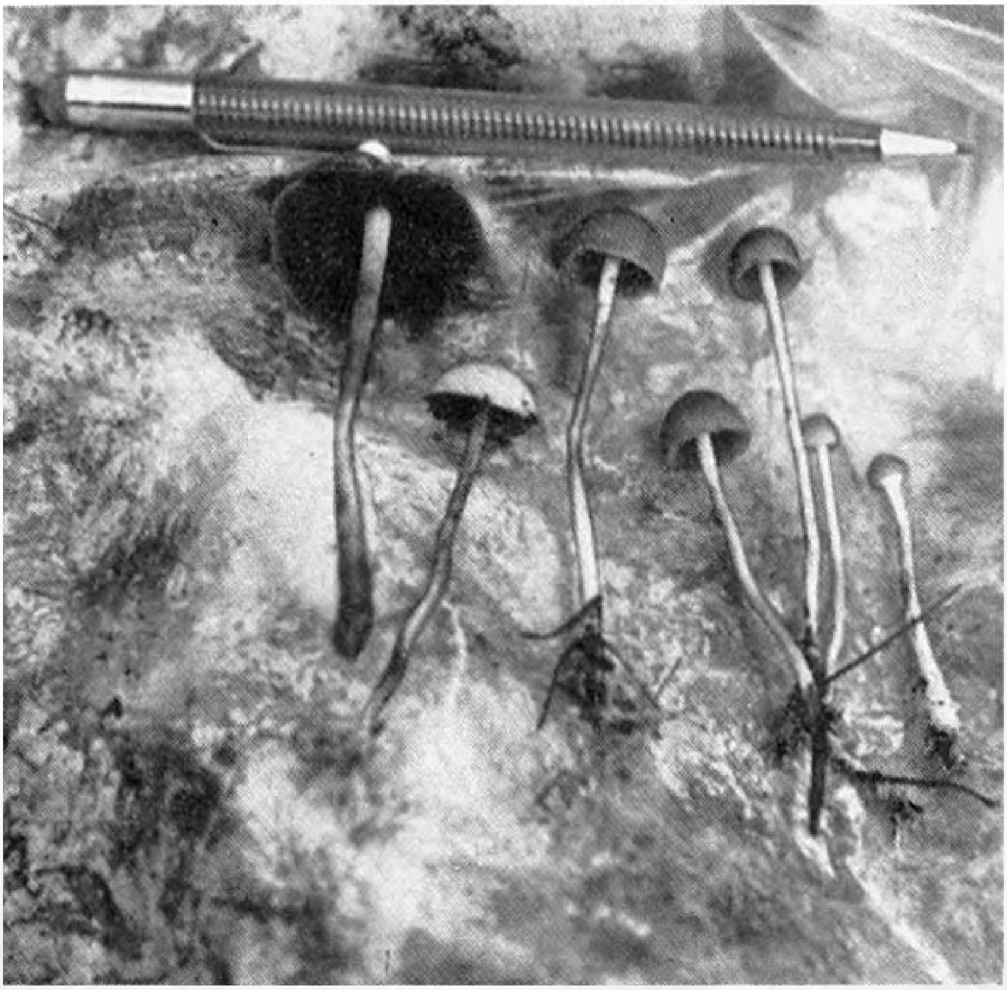
It has been no secret during the last four centuries that the Mexican Indians, particularly the ancient Aztecs and Mayas, used mushrooms as narcotics and that they had hallucinations during their narcotic states. This fact was used by the priests to make it appear that the visions of the mushroom-eater were divine revelations, attributed to a number of the heathen gods of pre-Columbian Mexico. It is also known that this knowledge continues with the present-day tribes of Mexican Indians, particularly with the Mazatec, Zapotec, and other Indians of southern Mexico and even in regions quite close to Mexico City, although there the ceremonies are held secretly in the houses of the curanderos (healers) under the pretense that they will provide cures for a large number of diseases.

However, the nature of the mushrooms involved was a secret to be disclosed by mycologists, the mushroom specialists among botanists. For there was a school of thought, as late as in the thirties, assuming that what the Spanish conquistadores had reported as mushrooms were actually cacti - the same cacti that are still used for comparable hallucinatory effect, peyotl (*Lophophora williamsii*). Then an American botanist, Richard Evans Schultes, brought some specimens to Harvard University, proving that what the Aztecs called teonanácatl (the sacred mushroom) actually was a mushroom. One of the species brought to Harvard was later proved to be inactive, i.e., not producing hallucinations in the sense described. The other specimen, however, was identified as *Psilocybe cubensis* by the writer, then mycologist at Harvard University. This mushroom grows on dung throughout the warm zones of the world and is remarkable because it has a ring-like structure on its stem (like the commercial white mushroom) and turns blue where scratched (because of the presence of an enzyme causing the oxidation of a colorless substance whereby it forms a melanin-like pigment, related to the one responsible for the color of human hair). San Isidro, the Mexican name of this mushroom, establishes again the relation with religion (Roman Catholic). The Mazatec Indians of the state of Oaxaca, living far away from civilization, continue eating this mushroom, six or eight fruiting bodies at a session, in order to get "where God lives," i.e., in a state of euphoria and colorful visions.

Since then two mycologists have gone to Mexico to study these mushrooms on the spot and obtain pure test-tube cultures in order to grow them in mushroom houses or industrially at home. Both Roger Heim, Director of the Museum of Natural History, Paris, and the writer have found that the San Isidro mushroom is not the only one eaten. Actually several species are eaten in various parts of Mexico, but all belong to the same taxonomic group, a section of the genus *Psilocybe*. They turned out to be either of worldwide distribution, like San Isidro, or from a more restricted area in America, like the so-called landslide mushroom (*Psilocybe caerulescens*), which was in fact discovered years ago in Alabama and called "birdies" by the Indians because they made one sing happily, and like *Psilocybe mexicana*, which grows in Mexico and Guatemala. Others were found only in a single region and were new to science.



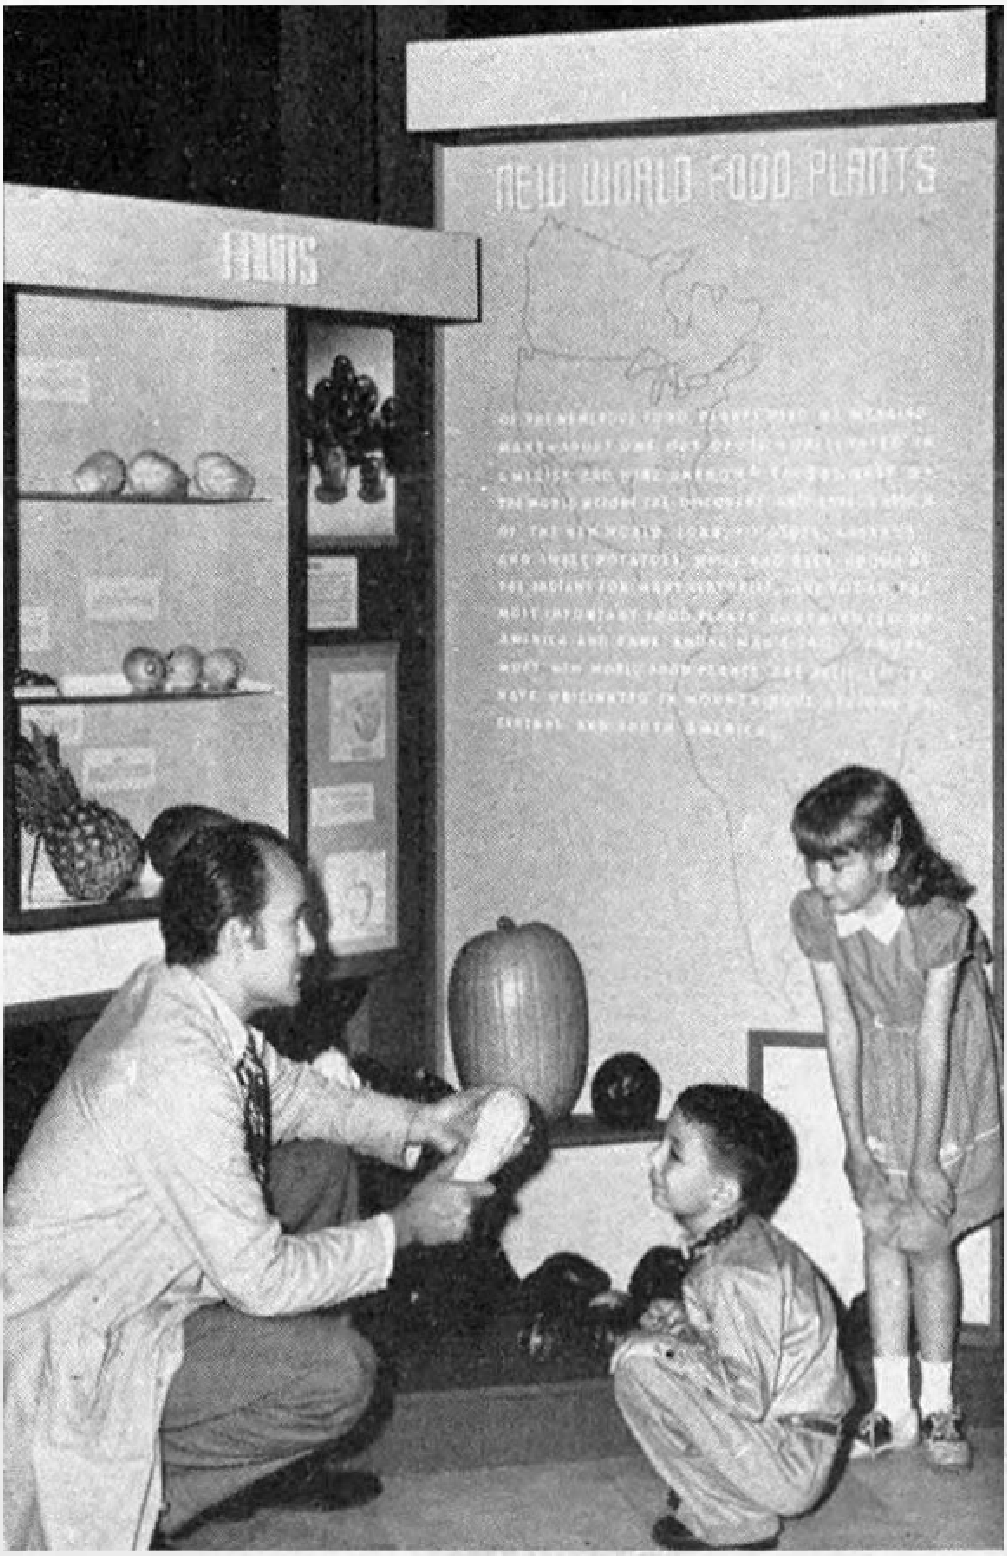
Sacred mushrooms
Representing one of several kinds of sacred mushrooms, specimens above (*Psilocybe aztecorum* Heim) were collected at Paso de Cortes, Mexico.

Why was there such a sudden outburst of activity in behalf of investigations into the subject of hallucinogenic mushrooms? There are several reasons. In the first place, as in so many cases, the time was ripe and our knowledge sufficiently widened during an intensive study of the anatomy and distribution of all fungi, especially of the mushroom-like "agarics" and "boletes," that it was now possible to tackle this difficult problem from the mycological side. Furthermore, a New York banker, Mr. R. Gordon Wasson, had become interested in the anthropological aspect and the folkloric role that these mushrooms have in Mexico and elsewhere in the world. He was so enthusiastic about his discoveries during several trips to Mexico that he published well-illustrated articles in several American and foreign magazines and, in addition, wrote a two-volume book on *Mushrooms, Russia, and History*. Finally, and this is perhaps the strongest incentive in our practical world that will not cease asking "what is all this *good* for?" - there is hope that the hallucinogenic principle in the mushrooms can be isolated and applied in medicine. We do not know precisely in which form this substance (or these substances) may be useful. Some believe that it may give us a better understanding of such mental disorders as schizophrenia, others think that it may become a new and better tranquilizer drug, and others believe that it might be directly applied to the mentally ill in a completely new approach to neuropsychiatric treatment.

Nothing is known thus far beyond the private observations of those who have eaten the mushrooms up in the mountains of Mexico in a weird surrounding and in a strange state of well-being and beauty in the midst of some of the oldest superstitions of this planet. Nevertheless, research is being driven far beyond the botanical aspect of the mushrooms, and while this is written several laboratories are busy with animal tests, chemical extractions, and analyses, and the scene is being made ready for the first tentative application in hospitals. A new wonder drug? Maybe, and maybe not, but most certainly one of the most intriguing and inspiring researches of our time, and well worth the curiosity demonstrated by scientists of all specialities.

A special exhibit in Chicago Natural History Museum's Stanley Field Hall from December 13 through January

19 will show models of the more common species used, as well as dried mushrooms and the test-tube cultures as obtained in a Mazatec Indian village in Oaxaca. Some kinds produce little mushrooms right inside the tube, others in order to fruit must be grown in a special mushroom house. The various species in dried condition are still useful and have not lost any of their hallucinogenic properties. They are soaked in water and eaten raw. Their taste is astringent and disagreeable.



Special exhibit
Samuel H. Grove, Jr., Artist-Preparator for the Department of Botany, discusses November special exhibit, "New World Food Plants," with two interested onlookers, Steve Kelemen and Esther Dycus, both of Griffith, Indiana.

Microdosing Psychedelics: Personality, mental health, and creativity differences in microdosers

Abstract

Microdosing psychedelics - the regular consumption of small amounts of psychedelic substances such as LSD or psilocybin - is a growing trend in popular culture. Recent studies on full-dose psychedelic psychotherapy reveal promising benefits for mental well-being, especially for depression and end-of-life anxiety. While full-dose therapies include perception-distorting properties, microdosing may provide complementary clinical benefits using lower-risk, non-hallucinogenic doses. No experimental study has evaluated psychedelic microdosing, however; this pre-registered study is the first to investigate microdosing psychedelics and mental health. Recruited from online forums, current and former microdosers scored lower on measures of dysfunctional attitudes and negative emotionality and higher on wisdom, open-mindedness, and creativity when compared to non-microdosing controls. These findings provide promising initial evidence that warrants controlled experimental research to directly test safety and clinical efficacy. As microdoses are easier to administer than full-doses, this new paradigm has the exciting potential to shape future psychedelic research.

1. Introduction

Microdosing psychedelics - the practice of regularly consuming very low doses of psychedelic substances such as lysergic acid diethylamide (LSD) or psilocybin ("magic" mushrooms) - is a growing practice despite a lack of scientific research validating its effects. One online microdosing forum (/r/microdosing subreddit, Reddit Inc, San Francisco, CA, USA) has almost 40,000 subscribers and doubled its subscriber count in the past year (Figure 1). The popular media has described consumption of psychedelics in doses much lower than typical therapeutic doses (Fadiman, 2011; Leonard, 2015; Solon, 2016; Waldman, 2017) and articles and anecdotes claim benefits including improved mood, focus, and creativity alongside decreased symptoms of depression and anxiety. While decreased depression and anxiety are consistent with research on full-dose psychedelics (Carhart-Harris *et al.*, 2017; Griffiths *et al.*, 2016), microdosing could offer these benefits without any perceptual distortions and reduced need for expensive clinical oversight typical of full-dose psychedelic psychotherapy. Nevertheless, both LSD and psilocybin are controlled substances in most countries and so members of the public enticed by purported benefits of microdosing expose themselves to the risks implied by criminalized activity. For example, in the US, LSD and psilocybin are schedule I controlled substances, meaning that they have no accepted therapeutic use. Such risks are exacerbated by an absence of even minimal scientific evidence that normally surrounds clinical use, such as data on safety, efficacy, common side-effects, contraindications, and appropriate dose and dose schedule.

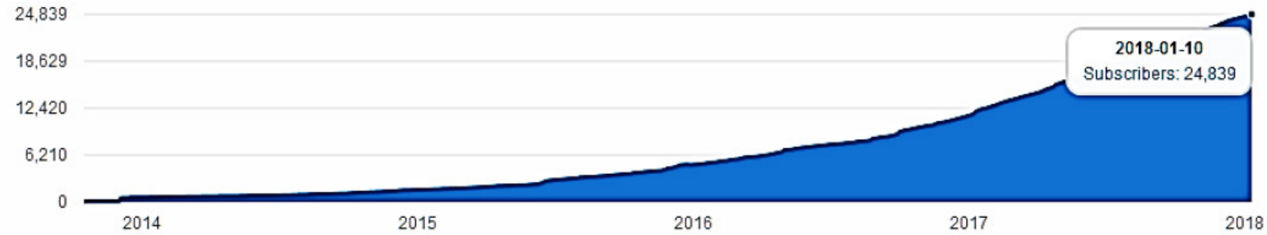

Figure 1. Rise in subscribers to an online microdosing forum, Reddit.com/r/microdosing. As of October 2018, the subscriber count has reached nearly 40,000 subscribers, doubling in less than one year.

It is unlikely that normative standards for microdosing will emerge without an initial description of current microdosing practices and associated outcomes. We therefore measured self-reported practices and psychological function of participants in existing microdosing communities and compared them to control participants with no microdosing experience. This design allows for a structured description of the common practices used in microdosing from which future clinical trials can build.

1.1 Full-dose Psychedelics

Interest in microdosing is likely predicated on research linking clinical benefits to full-dose psychedelic use. By 1975, over one thousand studies had linked psychedelic substance use with salutary effects on mental health and personal growth (Greenspoon & Bakalar, 1979). More recent research suggests efficacy for a number of health conditions, including obsessive compulsive disorder (Moreno *et al.*, 2006), alcohol dependence (Bogenschutz *et al.*, 2015), tobacco dependence (Johnson *et al.*, 2014), depression (Carhart-Harris *et al.*, 2017; Osório *et al.*, 2015), and end-of-life anxiety (Griffiths *et al.*, 2016; Ross *et al.*, 2016).

While research on psychedelics provides evidence for the therapeutic effects of full-doses, such experiences are often quite intense thus confer substantive participant risk. Popular vernacular includes the term "bad trip", and, indeed, one study participant described a full-dose experience as "the worst experience of her life" (Griffiths *et al.*, 2011). In an online survey of the worst "bad trips" experienced, 39% percent of participants rated their psychedelic experience among the top five most challenging experiences of his/her lifetime (Carbonaro *et al.*, 2016). At the same time, Carbonaro *et al.* (2016) also found that despite the difficult experiences, 84% of participants reported benefitting from the experience. Although research on LSD and psilocybin suggest low risks for abuse or harmful effects (Amsterdam *et al.*, 2011; Halpern and Pope, 1999; Johnson *et al.*, 2018), a small percentage of users are at risk of developing persisting perceptual effects (Hallucinogen Persisting Perception Disorder; Martinotti *et al.*, 2018) or risk being hospitalized for acute intoxication, especially if mixed with alcohol (Hardaway *et al.*, 2016). While large population studies suggest that psychedelics are not usually associated with detrimental mental health outcomes (Krebs & Johansen, 2013), microdosing may circumvent this issue as anecdotal reports suggest numerous positive outcomes without the risks associated with acute full-dose intoxication (Fadiman, 2011).

1.2 The Present Study

In this study we describe the psychological profile of the growing microdosing community by making comparisons against a population of non-microdosers. We compared groups of self-described microdosers (current and former microdosers) against controls (no microdosing experience) across a variety of mental health and personality variables. These include dysfunctional attitudes (de Graaf *et al.*, 2009), wisdom (Glück *et al.*, 2013), negative emotionality and open-mindedness (Soto and John, 2016), and creativity (Silvia, 2011). This study is part of a larger project that also reports on the demographics and psychiatric history of microdosing users (Rosenbaum *et al.*, 2018). A qualitative report examining subjective benefits and drawbacks of microdosing is also in preparation (Anderson *et al.*, 2018). We presently address pre-registered hypotheses about the outcomes associated with microdosing experience on validated scales.

2. Methods

2.1 Pre-Registered Hypotheses

Prior to data collection this study was pre-registered on the Open Science Framework (OSF; https://osf.io/ke49d/). We define "Microdosers" as those participants with experience microdosing, whether current or former use. We pre-registered the following hypotheses:

Mental Health Vulnerability, Wisdom, and Personality

While the mechanisms driving psychedelic substances' clinical efficacy are unclear, several psychological constructs are likely involved. These include practical indicators of flourishing, such as freedom from dysfunctional beliefs about oneself, other people, and the world; wisdom; and personality traits, especially neuroticism and openness to experiences.

Psychedelic substances are purported to have profound effects on one's understanding of the self and world, leading to enhanced insight and personal growth (Domínguez-Clavé *et al.*, 2016; Dos Santos *et al.*, 2016; Kometer *et al.*, 2015; Strassman, 2016). As such, we hypothesized that microdosers would have lower dysfunctional attitudes and higher wisdom than non-microdosers. Furthermore, improved mood and reduced mental health concerns are commonly reported outcomes of microdosing online (/r/microdosing subreddit, Reddit Inc, San Francisco, CA, USA). For this reason, we hypothesized that microdosers would have lower negative emotionality (depression, anxiety, and emotional volatility) than non-microdosers. Finally, participants experiencing a single full dose of psilocybin showed a robust and sustained increase in openness (MacLean *et al.*, 2011); we therefore predicted that microdosers would also have higher openness.

H1a: Microdosers will have lower dysfunctional attitude scores than non-microdosers.
H1b: Microdosers will have higher wisdom scores than non-microdosers.
H1c: Microdosers will have lower negative emotionality scores than non-microdosers.
H1d: Microdosers will have higher open-mindedness scores than non-microdosers.

Creativity

The Broaden and Build theory (Fredrickson, 2004) proposes a link between positive emotions and relaxed cognitive constraints as improved well-being may recruit personal resources in the generation of creative ways of coping with challenges. Enhanced creativity is one of the commonly reported outcomes of microdosing in media reports (Solon, 2016) and online (/r/microdosing subreddit, Reddit Inc, San Francisco, CA, USA) and is often reported as a benefit of full-dose psychedelics (Fadiman, 2011).

H2: Microdosers will have higher creativity scores than non-microdosers.

Importance of Benefits

Participants were asked to rate how important qualitative benefits of microdosing were to them. We used this measure of subjective "importance of benefits" as a broad outcome of participants' positive valuation of microdosing. Based on online anecdotal reports we predicted that there would be a total-dose response curve such that microdosers would rate the importance of benefits as quickly increasing to a plateau. Concerning dose scheduling, James Fadiman (2011) proposed a dose-schedule such that microdosers consume their substance one day, then refrain for two days, then dose again; we hypothesized that this schedule would show optimal reported importance of benefits compared to alternate dose frequencies, perhaps due to substance-tolerance (more frequent) or limited efficacy (less frequent).

Total Doses and Dose Frequency

H3a: A logarithmic relationship will exist between total lifetime microdoses and average reported importance of benefits. Specifically, benefits are expected to be minimal with minimal total doses, then increase, and subsequently stabilize at a plateau.
H3b: A quadratic relationship will exist between frequency of microdosing and average reported importance of benefits. Specifically, maximum benefits are expected when participants report frequency of microdoses at ~3 days between microdoses with reduced benefits for shorter and longer frequencies.

More frequent and more intense positive experiences with a substance motivate future use of that substance (de Wit and Phillips, 2012). As such, microdosers with a more extensive history of full-dose psychedelic use may be especially motivated to try microdosing and may evaluate benefits of microdosing more highly. This positivity bias may extend beyond psychedelics as, more generally, substance use is associated with greater openness to experience (Gunnarsson *et al.*, 2008; Terracciano *et al.*, 2008; Trull and Sher, 1994), which may include an openness to try novel pharmacological interventions, such as microdosing.

Substance-Use History

H4a: Microdosers reporting at least one life-time use of a classic psychedelic (LSD, psilocybin mushrooms, DMT, ayahuasca, mescaline) at full dose will report higher average importance of benefits than microdosers that have not had a full dose. H4b: Microdosers reporting greater variety of recreational substance use ("Polydrug user experience index", see below) will report higher average importance of benefits than microdosers with less recreational substance experience.

2.2 Deviations from Pre-Registration

A survey-flow error resulted in unintended data-collection on dose frequency and importance (H3 and H4) from participants with no experience microdosing; this data has been discarded.

2.3 Participants

Participant were snowball-recruited via social media (e.g. Facebook, Twitter) and recruited through posts on the online forum "reddit" (Reddit Inc, San Francisco, CA, USA): links were posted under the username /u/oredna on the following subreddits: Microdosing, Nootropics, Psychonaut, RationalPsychonaut, Tryptonaut, Drugs, LSD, shrooms, DMT, researchchemicals, and SampleSize. Both participants with experience and participants without experience microdosing psychedelics were recruited for this study. Participation was voluntary, and participants were not remunerated. The survey was in English and internationally available.

Participants exited the online survey at different stages of completion; different analyses therefore employ different numbers of participants. While 1390 respondents began the survey, 475 exited before responding, 3 requested that their responses be removed, and 3 responses were removed for disingenuous responding, i.e. "trolling". In total 909 participants entered enough data to be included in analyses, sorted into two categories: those with microdosing experience (Microdosers: n = 594, 65%) and those without such experience (Non-microdosers: n = 315, 35%); full-dose experience with psychedelics was not considered for determining microdosing status. Of these participants 29% were currently microdosing (current microdosers), 37% had microdosed in the past but have since stopped (former microdosers), 30% were interested in microdosing but had no prior experience, and 4% had no prior experience and reported not being interested in microdosing. Participants from 29 countries responded to the survey (median age = 26, 82% males, 70% white). For a more comprehensive breakdown see the full epidemiological report (Rosenbaum *et al.*, 2018).

2.4 Design and Questionnaires

Following informed consent, participants completed online computer-based questionnaires (https://osf.io/jmcrh/) including questions pertaining to microdosing habits (substance, frequency, dosage), substance use and mental health history, dispositional personality variables (Dysfunctional Attitudes, Wisdom, Negative Emotionality, Open-Mindedness), and a creativity task. Questions were displayed according to experience with microdosing, i.e. individuals who reported never having microdosed were not shown questions related to a history of microdosing (note survey flow error, 1.4.1 above). For uniformity, all scales were rated using a continuous 0-100 slider-scale with nominal descriptors at 0 ("Disagree Strongly") and 100 ("Agree Strongly") (Matejka *et al.*, 2016). For brevity, methods reported here focus on variables analyzed in this paper; a complete list of all questions is available on the OSF pre-registration.

2.4.1 Microdosing Substance

The majority of participants reported using LSD (65%) and/or Psilocybin (28%) for microdosing; 16% reported using another substance. For a more comprehensive breakdown see the full epidemiological report (Rosenbaum *et al.*, 2018).

2.4.2 Mental Health Vulnerability

The DAS-A-17 is a short-version of the Dysfunctional Attitude Scale, a 40-item self-report scale designed to measure the presence and intensity of dysfunctional beliefs (de Graaf *et al.*, 2009). Participants rate statements of beliefs (e.g. "If I fail at my work, then I am a failure as a person.") on a 7-point Likert scale and the total score is the sum of the 17-items (range: 17-119) with higher scores indicating more dysfunctional attitudes (Weissman and Beck, 1978). The DAS-A-17 includes a total-score and two subscales: "perfectionism/performance evaluation" (11 items) and "dependency" (6 items). Reliability for total score was excellent (α = 0.91) and good for the subscales (perf: α = 0.87, dep: α = 0.85).

A Mental Health Index of psychological disorders was computed as a simple binary 0/1 based on the question, "Have you ever been diagnosed by a doctor or health care professional (e.g., psychiatrist, psychologist) with any of the following diagnoses", which was followed by a list of DSM-V diagnoses. Endorsing any diagnosis was coded as a "1", otherwise "None of the above" was coded as "0". Comprehensive findings will be available in the epidemiological report (Rosenbaum *et al.*, 2018).

2.4.3 Wisdom

The Brief Wisdom Screening Scale (BWSS, (Glück *et al.*, 2013) was developed by selecting the 20 items that were most highly correlated with the common factor of "wisdom self-report" across three leading wisdom self-report measures. Reliability was good (α = 0.86).

2.4.4 Personality

The Big Five Inventory 2 (BFI2, Soto and John, 2016) is an updated five-factor personality measure using the commonly recognized five-factor model: Extraversion, Agreeableness, Conscientiousness, Negative Emotionality (formerly "Neuroticism"), and Open-Mindedness (formerly Openness to Experience). Our hypotheses were centered on two of these subscales: Negative Emotionality and Open-Mindedness, thus only these factors were measured. Reliability was good (Negative Emotionality α = 0.91, Open-Mindedness α = 0.79).

2.4.5 Creativity

The Unusual Uses Task is a task in which participants generate creative uses for mundane objects (UUT; (Silvia, 2011)). The UUT instructions emphasized the importance of original responses, reading "Please try and think of the most unusual, creative, and uncommon uses you can imagine" (Harrington, 1975). Participants were asked to give as many responses as they could for each of two items (brick, knife), allotted one minute for each. During analysis, responses were split into alphabetical lists to avoid within-participant biases. Responses were rated by three independent research assistants using three dimensions: uncommon, clever, and remote (Silvia *et al.*, 2008). Dimension-scores across objects were averages to produce three dimension-scores. Intraclass correlation coefficient was moderate for each dimension (Uncommon: 68.25, Remote: 57.25, Clever: 59.75) and moderate for each object (brick = .61, knife = .64).

2.4.6 Importance of Benefits

Participants rated qualitative benefits of microdosing in terms of personal, subjective importance for three self-generated benefits. The average of these scores was then used as a broad index of participants' subjective valuation of microdosing, analyzed in H3/4 in this study. A taxonomy that organizes the participant-generated benefits has been generated using Grounded Theory analysis and will be featured in an independent report (Anderson *et al.*, 2018).

2.4.7 Microdosing Frequency

Microdosers reported the total number of lifetime microdoses taken (0 to 100). They also reported dose scheduling, that is, the number of days spaced between each microdose (dose every day to dose once every two months).

2.4.8 Substance-Use History

To test H4 concerning substance-use history, participants reported their experience with full-dose psychedelics and with other substances. We developed a novel index: the "Polydrug User Experience Index". This novel measure was computed as the sum of recreational experiences across 13 classes of substance (e.g. Alcohol, Cannabis, MDMA, Stimulants, Opiates, Dissociatives, etc.) accounting for recency of experience. Each class of substance was scored according to the following metric: (a) used in past month: +4 points; (b) used in past year: +2 points; (c) used ever: +1 point; (d) never used: +0 points; (e) Prefer not to answer: +0 points. Scores range from 0-52, with lower scores indicating less experience with recreational substance use.

2.4.9 Mood

A "Valence" score was computed using a mood-board (https://osf.io/jmcrh/) as the count of pleasant minus unpleasant items, as was an "Arousal" score for high-intensity minus low-intensity moods.

3. Results

Table 1. Contrast between Microdosers and Non-Microdosers, means with standard deviations and standardized effect-sizes.

Variable	Microdoser	Non-Microdoser	Effect size d [95% CI]
Age	27.23 (8.94)	26.36 (7.78)	0.1 [-0.04 , 0.25]
Education[1]	4.72 (1.72)	4.78 (1.77)	-0.03 [-0.18 , 0.11]
SES[2]	0.50 (1.33)	0.51 (1.40)	-0.01 [-0.15 , 0.14]
Mood - Valence	2.33 (4.40)	-0.16 (4.14)	**0.58 [0.44 , 0.72]**
Mood - Intensity	-0.08 (2.42)	0.02 (2.40)	-0.04 [-0.18 , 0.09]
Dysfunctional Attitudes (DAS-17)[3]	40.62 (16.28)	49.30 (16.33)	**-0.53 [-0.77 , -0.29]**
Wisdom (BWSS)	66.68 (13.16)	60.05 (12.98)	**0.51 [0.27 , 0.74]**
Negative Emotionality (BFI-2)	41.53 (20.06)	48.16 (18.89)	**-0.34 [-0.56 , -0.11]**
Open-Mindedness (BFI-2)	76.43 (12.44)	73.33 (13.16)	**0.25 [0.02 , 0.47]**

1 - Education was coded according to the International Standard Classification of Education (UNESCO Institute for Statistics, 2011): ISCED level 0 = Early childhood education, 1 = Primary education, 2 = Lower secondary education, 3 = Upper secondary education, 4 = Post-secondary non-tertiary education Tertiary education, 5 = Short-cycle tertiary education, 6 = Bachelor's or equivalent level, 7 = Master's or equivalent level, 8 = Doctoral or equivalent level
2 - Socio-Economic Status (SES) was coded as: -3 = Non-working class (casual workers, pensioners, or dependents); -2 = Working class (semi-skilled or unskilled manual workers); -1 = Skilled working class (skilled manual workers); 0 = Lower-middle class (junior managerial, administrative, or professional); 1 = Middle class (intermediate managerial, administrative, or professional); 2 = Upper-middle class (higher managerial, administrative, or professional); 3 = Upper class (royalty or immense heritable wealth).
3 -DAS scores have been transformed to the original DAS-17 scale (17-119).

Table 2. Follow-up Analysis of Microdosers (Current versus Former), means with standard.

Variable	Current Microdoser	Former Microdoser	Effect size d [95% CI]
Age	28.89 (9.71)	25.93 (8.06)	**0.33 [0.16 , 0.51]**
Education	4.83 (1.70)	4.64 (1.73)	0.11 [-0.06 , 0.28]
SES	0.48 (1.34)	0.52 (1.32)	-0.03 [-0.2 , 0.14]
Mood - Valence	2.93 (4.57)	1.86 (4.21)	**0.24 [0.08 , 0.41]**
Mood - Intensity	0.10 (2.38)	-0.23 (2.45)	0.14 [-0.03 , 0.3]
Dysfunctional Attitudes (DAS-17)	39.53 (14.58)	41.53 (17.56)	-0.12 [-0.36 , 0.11]
Wisdom (BWSS)	66.09 (12.86)	67.18 (13.42)	-0.08 [-0.32 , 0.15]
Negative Emotionality (BFI-2)	43.32 (19.98)	39.95 (20.07)	0.17 [-0.06 , 0.4]
Open-Mindedness (BFI-2)	77.06 (11.91)	75.87 (12.91)	0.09 [-0.13 , 0.32]

3.1 Pre-Registered Hypotheses and Planned Follow-up Analysis

3.1.1 Mental Health Vulnerability, Wisdom, and Personality

Mental Health Vulnerability

Microdosing predicted lower scores on Dysfunctional Attitudes (b = -8.69, 95% CI [-12.48 -4.89], z(364) = -4.49, $p < .001$, *r* =-0.92), even when controlling for a history of mental illness, which was also significant (b = 5.74, 95% CI [2.45 9.03], z(364) = 3.42, $p < .001$, *r* = 0.85) (Figure 2). Dysfunctional Attitudes were not related to current versus former microdosing (b = 1.90, 95% CI [-1.91 5.71], *p* = 0.33), nor to type of substance used (LSD vs Psilocybin: b = 0.56, 95% CI [-4.93 6.05], *p* = 0.842), nor to total number of lifetime microdoses (b = -1.66, 95% CI [-3.47 0.15], *p* = 0.074).

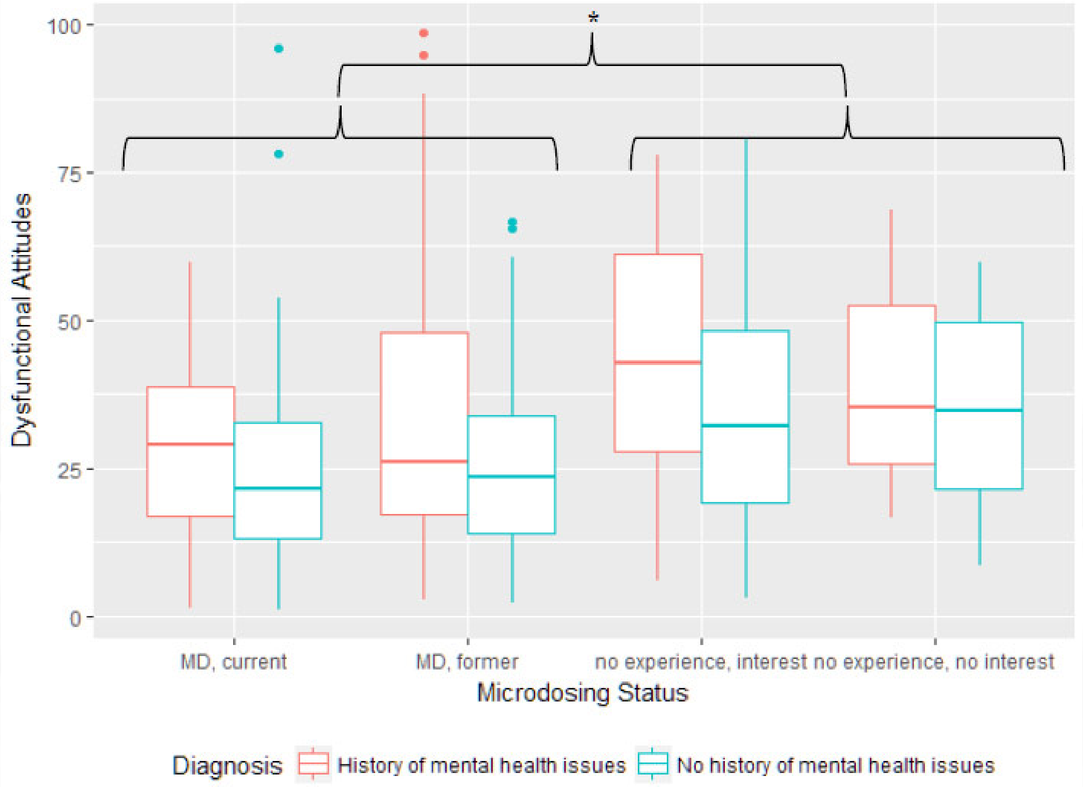

Figure 2. Differences in dysfunctional attitudes between microdosers and non-microdosers including breakdown by history of mental illness. The asterisk (*) indicates a significant main effect of microdosing status such that microdosers showed lower dysfunctional attitudes than non-microdosers ($p < 0.001$). Respondents with no history of mental illness (blue) also had lower dysfunctional attitudes than those with a history of mental illness (orange, $p < 0.001$), though microdosing status was a significant predictor even controlling for this potent covariate.

Wisdom

Microdosing predicted higher wisdom scores (b = 6.61, 95% CI [3.52 9.69], z(367) = 4.19, $p < .001$, *r* = 0.88) when controlling for age and level of education, which were not significant (age: b = -0.11, 95% CI [-0.26 0.04], *p* = 0.16, education: b = 0.40, 95% CI [-0.43 1.24], *p* = 0.35). No significant differences were found between current and former microdosers * (b = 1.09, 95% CI [-1.96 4.13], *p* = 0.48), nor type of substance used (b = 1.37, 95% CI [-2.83 5.57], *p* = .523), nor total lifetime number of microdoses (b = 0.62, 95% CI [-0.80 2.05], *p* = 0.39).

Negative Emotionality

Microdosing predicted lower Negative Emotionality (b = -5.78, 95% CI [-10.13 -1.43], z(396) = -2.60, *p* = .009, *r* = -0.85), even after controlling for gender, which was also a significant predictor (higher Negative

Emotionality in females, b = 10.49, 95% CI [5.33 15.65], z(396) = 3.99, *p* < .001, *r* = 0.95). Planned follow-up analysis tested the difference between current and former microdosers and no significant difference existed between the groups (b = -2.95, 95% CI [-7.47 1.58], *p* = 0.20), nor between substance used (b = -5.18, 95% CI [-11.50 1.15], *p* = .110), nor any effect of lifetime number of microdoses (b = -0.25, 95% CI [-2.38 1.89], *p* = 0.82) on Negative Emotionality.

Open-Mindedness

Microdosing predicted greater Open-Mindedness (b = 3.24, 95% CI [0.38 6.10], z(392) = 2.22, *p* = .027, *r* =0.67), including when controlling for education, which was not significant (b = 0.08, 95% CI [-0.65 0.81], *p* = 0.83). Again there were no significant differences between current and former microdosers (b = -1.18, 95% CI [-4.00 1.64], *p* = 0.41), nor type of substance used (b = 1.35, 95% CI [-2.61 5.31], *p* = .506), nor total lifetime number of microdoses (b = 0.77, 95% CI [-0.55 2.09], *p* = 0.26).

3.1.2 Creativity

Microdosing predicted higher scores on all three creativity facets: on average, responses made by microdosers were more clever (b = 0.57, SE = 0.13, z(423) = 4.25, *p* < .001, *r* =0.15), more uncommon (b = 0.50, SE = 0.15, z(427) = 3.42, *p* < .001, *r* =0.14) and more remote (b = 0.74, SE = 0.16, z(425) = 4.49, *p* < .001, *r* =0.20).

3.1.3 Importance of Benefits

Self-reported "importance of benefits" was intended to reflect participants' broad valuation of microdosing. Counter to H3a/b, no significant differences were found in reported importance of benefits when regressed on lifetime microdoses (b = 1.01, 95% CI [-0.81 2.82], *p* = .277) nor frequency of microdosing regardless of explored linear and non-linear relationships (raw: b = -0.07, 95% CI [-0.66 0.53], *p* = 0.83; squared: b = -0.0004, 95% CI [-0.01 0.01], *p* = 0.94; logarithmic: b = 1.21, 95% CI [-2.68 5.09], *p* = 0.54). Counter to H4a/b there were also no significant difference in the importance of benefits between participants who had previous experience with full-dose classic psychedelics and those who had no such experience (b = -4.09, 95% CI [-11.80 3.61], *p* = 0.30) nor based on the variety and recency of recreational substance use (Polydrug User Experience Index: b = -0.006, 95% CI [-0.26 0.25], *p* = 0.96).

3.2 Exploratory Analysis

Exploratory comparison of mood measures (valence and intensity, Tables 1&2) by Welch's *t*-test revealed that microdosers reported significantly more positive valence (M=2.33, SD=4.40) than non-microdosers (M=-0.16, SD=4.14; difference: 2.49, 95% CI [1.91 3.07], t(675) = 8.44, *p* < .001, *r* =0.31). No differences were found for mood intensity (difference: - 0.11, 95% CI [-0.44 0.22] *p* = 0.53). For valence, current microdosers (M=2.93, SD=4.57) also reported more positive valence than former microdosers (M=1.86, SD=4.21; difference: 1.07, 95% CI [0.35 1.79], t(533) = 2.92, *p* = .004, *r* =0.13), but no difference in mood intensity (difference: 0.33, 95% CI [-0.06 0.72], *p* = 0.10).

4. Discussion

This is the first preregistered report on microdosing psychedelics and is intended to inform future lab-based clinical intervention studies. We investigated psychedelic microdosing in online communities and tested pre-registered hypotheses (Anderson *et al.*, 2017) concerning the relationship between experience with microdosing and various mental health and personality variables. Our results suggest a beneficial relationship wherein experience with microdosing is associated with lower dysfunctional attitudes and negative emotionality and higher wisdom, open-mindedness, and creativity. The most popular substances used to microdose were LSD and psilocybin, and no significant differences based on substance were found on our quantitative measures. The qualitative benefits and drawbacks collected in this survey may yet reveal substance-based effects (Anderson *et al.*, 2018). Hypotheses predicting perceived importance of microdosing from dose-related practices were unsupported and optimal dose scheduling remains an open question. Exploratory analyses revealed that microdosers, especially current microdosers, had more positive emotional valence than non-microdosers, whereas emotional intensity was not significantly different. Taken together, these findings suggest that randomized, placebo-controlled clinical trials (RCTs) of microdosing are warranted to investigate the causal efficacy of microdosing.

Consistent with our hypotheses, microdosing experience was associated with meaningfully lower levels of dysfunctional attitudes. Individuals with higher dysfunctional attitudes maintain a set of disadvantageous beliefs that increase vulnerability to stressors (Jarrett *et al.*, 2012) and high scores are associated with depression (Adler *et al.*, 2015; de Graaf *et al.*, 2009). Also consistent with our hypotheses was the lower negative emotionality seen in microdosers, though the estimated effect was less precise. Tendencies to experience negative emotionality (e.g. anxiety, depression, emotional volatility) are a robust predictor of mental and physical health problems (Lahey, 2009) thus reduced vulnerability is reflected in the lower scores seen in microdosers. Exploratory analysis revealed that microdosers had more positive emotional valence than non-microdosers, linking microdosing to better mood states. While causation cannot be inferred from these results, significant differences were preserved even after controlling for potent covariates, such as gender and history of mental illness, indicating a potentially distinct contribution of microdosing on mental health vulnerability that warrants further study.

Microdosers also had higher wisdom, which is a complex trait (BWSS, Glück *et al.*, 2013). As measured by the BWSS, wisdom is understood to reflect learning from one's mistakes, considering multiple perspectives when facing a situation, being in tune with one's own emotions and the emotions of others, and feeling a sense of connection and unity. Higher scores, as seen in this sample of microdosers, may be associated with cognitive and emotional processing differences including enhanced capacity for perspective taking, resilience in the face of the vicissitudes of life, and increased feelings of engagement and connection. RCT research addressing the relationship between wisdom and microdosing are warranted.

Greater open-mindedness was expected in microdosers compared to controls due to previous studies noting increases in openness following a full-dose of psilocybin (MacLean, Johnson, & Griffiths, 2011). These differences were supported, though this effect was relatively weaker than the others. Still, given the findings from full-dose psychedelic studies, future clinical intervention research should continue investigating any causal relationship between open-mindedness and microdosing.

Microdosers were more creative when finding unusual uses for household items. This is consistent with Fredrickson's (2004) Broaden and Build theory, which suggests a positive relationship between creativity and positive affect, which was also seen in microdosers. Happier, more creative people may be more likely to apply novel modes of thinking in their personal and interpersonal challenges (Fredrickson, 2004). Our findings are also consistent with the anecdotal reports that a relationship between microdosing, creativity, and mood exists, but RCTs, ideally with multiple creativity measures, are required.

None of our hypotheses concerning the importance of microdosing benefits and microdosing practices were supported. It is likely that this measure was not sensitive and specific enough; planned analyses of qualitative benefits and drawbacks of microdosing will be explored in a separate report (Anderson *et al.*, 2018). It may be that microdosing frequency is truly unrelated to the subjective valuation of microdosing, but this seems improbable. We suggest that this research question is best addressed in RCT studies focused on specific benefits with experimental manipulation of dose and schedule to determine optimal benefit-specific protocols. Similarly, there is no evidence that outcomes are predicated on prior experience with substances, whether full-dose psychedelics or with a variety of substances. More microdosers had experience with full-doses (69%, *n*=412) then did not (31%, *n*=182) and many microdosers (and nonmicrodosers) had experience with full-dose psychedelics within the month prior to completing the survey. As full-dose psychedelics can have benefits lasting at least a month (Carhart-Harris *et al.*, 2017) this covariate should be formally modelled in future microdosing research designs, which should aim to include both psychedelic-naïve and psychedelic-experienced participants.

5. Limitations and Future Directions

The sample is both a strength and a limitation of this study. This sample represents a true community of microdosers with dozens of countries represented, however, countries in the Anglo cultural cluster make up the majority of the sample (>70%) and participants were predominantly middle-class, white, male, and heterosexual. Sampling from online communities, including Reddit, could create a demographic bias thus we cannot suggest a definitive epidemiological generalization. Despite this limitation, this sample does inform us about real community practices in an otherwise unstudied population and reflects our sample of interest.

A second limitation of this study is its correlational nature. This cross-sectional design contained no longitudinal component or experimental manipulation and cannot be used to infer causal relationships. Our findings of group-differences do not infer that microdosing caused these differences as some of the measured constructs may even promote an increased willingness to explore microdosing, e.g. open-mindedness. Instead, these findings are intended as a descriptive foundation upon which experimental and clinical studies of psychedelic microdosing can be designed, exploring the directionality of relationships established in the present study.

To test causal hypotheses concerning microdosing effects, pre-registered randomized placebo-control trials (RCTs) are needed. With random assignment to microdose or placebo it would be possible to determine whether microdosing causally influences mental health and personality. Following positive causal findings, mechanistic studies could then investigate the observed efficacy in terms of physiological, psychological, and neurobiological changes.

Promisingly, microdosing may prove easier to administer, monitor, and placebo-control in lab settings due to the absence of the intense perceptual shifts induced by full-doses. Microdosing may thus be amenable to designs that could aid in mapping the neural mechanisms behind psychedelic efficacy. Microdosing could also be explored as an adjunct to long-term psychotherapy predicated on the longitudinal cultivation of resilience and insight, a new paradigm that could compliment the acutely transformative model underlying high-dose psychedelic psychotherapy (Rosenbaum *et al.*, 2018).

6. Conclusion

This study provides initial, correlational evidence for mental health and personality benefits associated with microdosing psychedelics. While anecdotal reports of microdosing benefits have existed for some time (Fadiman, 2011), this study marks the first formal study of the topic. Additionally, the use of a pre-registered study design sets a precedent for responsible and replicable psychedelic microdosing research. To add depth to the current discussion, a full epidemiological report (Rosenbaum *et al.*, 2018) and a Grounded Theory analysis of qualitative outcomes (Anderson *et al.*, 2018) are forthcoming.

The results of the present study suggest that there is a significant relationship between microdosing experience and measures of mental health and flourishing including lower dysfunctional attitudes and negative emotionality, higher wisdom and open-mindedness, and higher creativity and affect-valence. These findings are the initial evidence that warrants RCTs to directly test safety and therapeutic efficacy. With almost 40,000 users subscribing to the /r/microdosing subreddit and thousands more reading media reports on microdosing this growing community continues to explore microdosing and its effects. It is our hope that scientific reporting can help to clarify and inform the public about the nature of microdosing's putative effects and that this new paradigm helps shape future psychedelic research. We hope that researchers will draw on our shared resources (https://osf.io/g5cwy/) and pre-register studies of their own so that psychedelic science will be built upon strong research practices. Insights from these and other studies will form the backbone of future research into microdosing psychedelics.

Conflict of interest statement
On behalf of all authors, the corresponding author states that there is no conflict of interest.

Responses to the microdosing critique reviews

Abstract

Background: In the past few years, the issue of 'microdosing' psychedelics has been openly discussed in the public arena where claims have been made about their positive effect on mood state and cognitive processes such as concentration. However, there are very few scientific studies that have specifically addressed this issue, and there is no agreed scientific consensus on what microdosing is.

Aim: This critique paper is designed to address questions that need to be answered by future scientific studies and to offer guidelines for these studies.

Approach: Owing to its proximity for a possible approval in clinical use and short-lasting pharmacokinetics, our focus is predominantly on psilocybin. Psilocybin is allegedly, next to lysergic acid diethylamide (LSD), one of the two most frequently used psychedelics to microdose. Where relevant and available, data for other psychedelic drugs are also mentioned.

Conclusion: It is concluded that while most anecdotal reports focus on the positive experiences with microdosing, future research should also focus on potential risks of (multiple) administrations of a psychedelic in low doses. To that end, (pre)clinical studies including biological (e.g. heart rate, receptor turnover and occupancy) as well as cognitive (e.g. memory, attention) parameters have to be conducted and will shed light on the potential negative consequences microdosing could have.

Keywords Psychedelics, microdosing, psychoactive substances.

Background

Psychedelics are a class of psychoactive substances that induce complex behavioural, psychological and physiological effects primarily through activation of serotonin 5-HT$_{2A}$ receptors. In the past few years, the issue of 'microdosing' psychedelics has been openly discussed in the public arena with several books (Cruz, 2017; Kumar, 2016; Waldman, 2017) claiming value to the authors who tried this concept. However, there are very few scientific studies that have specifically addressed this issue, and there is no agreed scientific consensus on what microdosing entails (Cameron *et al.*, 2019; Horsley *et al.*, 2018). This paper is designed to address questions that need to be answered by future scientific studies and to offer guidelines for these studies. Although a number of classic psychedelics exist, two of them, lysergic acid diethylamide (LSD) and psilocybin, are allegedly most frequently used to microdose. The following review focuses predominantly on psilocybin due to its proximity for a possible approval in clinical use and short-lasting pharmacokinetics (Passie *et al.*, 2002) in comparison with LSD (Dolder *et al.*, 2017). However, where relevant and available, data for other psychedelic drugs are also mentioned.

As early as the 16th century, low doses of psilocybin, '*teonanacatl*' or sacred mushroom, were used medically (Schultes, 1940). Bernardino de Sahagún, a Franciscan friar during the period of the Spanish conquest of the Americas (1519-1521), reported that, '*teonanácatl* were ... medicinal for fevers and for rheumatism. Only two or three need to be eaten. Those who eat them see visions and feel a faintness of the heart. And they provoke lust to those who eat a number, or even a few, of them'. However, by 1640, 94% of the Aztec population was wiped out and alongside them, the traditions involving '*teonanácatl*'. Of note, the mentioning of visions here suggests this ancient 'low-dose' use does not refer to what is currently seen as microdosing, something that will be addressed below.

Psychedelic studies underwent a significant expansion following the discovery of the mind-altering properties of LSD by Albert Hofmann in 1943 (Hofmann, 1970). The subsequent growth of psychedelic use allegedly had a profound effect on innovation in science and technology. A popular example is that of Francis Crick, one of the co-discoverers of the double-helix structure of DNA, who used LSD, though this use was never confirmed nor denied by him (Roberts, 2008). Furthermore, Kary Mullis, who discovered a means to automate the polymerase chain reaction, claimed that the idea came to him after using LSD (Doyle, 2002). These discoveries greatly advanced the field of genetic research (Luke, 2006). In this atmosphere of innovation, Frederick Terman was appointed as Provost of Stanford, 1955-1965. During his tenure, Terman 'set out to create a community of technical scholars in Silicon Valley' (Leslie and Kargon, 1996). This community developed alongside the psychedelic capital of the world, San Francisco, and over time technology and psychedelics began to merge. By 2005, the founder of Apple and one of the most influential figures in Silicon Valley, Steve Jobs, highlighted that LSD had played a pivotal and transformative role in his life (Dormehl, 2012).

Although there was accumulating evidence to suggest that the intake of psychedelics led not only to hallucinations but also to an improvement of cognition and creativity, scientific progress in the field was prohibited by government agencies on account of the growing political concern over the recreational use of psychedelics (Belouin and Henningfield, 2018). Thus, the only study investigating psychedelics in problem solving was ended by the US Food and Drug administration (FDA) in 1966 (Harman *et al*., 1966). However, James Fadiman, a young researcher in this study, continued his research after the UN Convention on Psychotropic Substances of 1971 banned psychoactive substances and bundled his knowledge into a book, which now acts as a guide for those interested in microdosing. His book The Psychedelic Explorer's Guide: Safe, Therapeutic, and Sacred Journeys (Fadiman, 2011) published in 2011, is often referred to as a protocol for those practising microdosing. Of note, no study to date has revealed statistically significant effects of microdosing on creativity under placebo-controlled circumstances (Passie, 2019).

Although microdosing became prominent due to the belief it improved cognition, a growing number of individuals began to microdose psychedelics to improve conditions of pain (Johnstad, 2018), cluster headache or migraine (Andersson *et al*., 2017). It seems that the efficacy of microdosing may derive from its non-psychedelic dose range, which provides treatment without affecting cognition. Individuals also reported relief of pain with a long-term psychedelic microdosing regimen (Johnstad, 2018). Thus, psychedelic microdosing might constitute a different paradigm to single psychedelic therapeutic sessions with *macrodoses* where the nature and content of the experience plays a key role in predicting therapeutic outcome (Roseman *et al*., 2018; Schenberg, 2018). However, many questions remain about the definition, safety, potential mechanism and future research involving microdosing.

Question 1: What does microdosing mean?

The term microdosing is not a uniquely psychedelic term. In pharmacology, microdosing is a process used in drug development (Lappin and Garner, 2008) and drug selection (Lappin *et al*., 2006) where a minute dose of a substance is used to assess the pharmacokinetics of a drug. A microdose, in this regulatory arena, has been defined by a position paper from the European Medicines Agency 2004 (EMEA, 2003), guidelines from the U.S. Food and Drug Administration in 2006 (FDA, 2006) and the Ministery of Health, Labour and Welfare in Japan in 2008 (MHLW, 2008), and the current definitive international guideline in 2009 (ICH, 2009) as being a dose of drug that is 1% of the pharmacologically active dose, up to a maximum of 100 µg. Thus, psychedelic microdosing ('5-10 µg of LSD' (Fadiman, 2011)) would be 5-10% of a usual psychoactive dose and lie between a full pharmacological dose (100%) and a 'pharmacological microdose'.

Microdosing psychedelics has been described in a similar manner by different individuals. Fadiman describes it as a practice 'to use sub-threshold doses of psychedelic drugs in an attempt to enhance cognitive tasks, to boost physical energy levels, to promote emotional balance, and to treat anxiety, depression and addiction' resulting in typically subtle though noticeable effects (Fadiman, 2011). Similarly, Aylet Waldman in her book (Waldman, 2017) states the same intention for microdosing but describes the process as 'the act of integrating sub-perceptual doses of psychedelic drugs, in your weekly routine'. In addition, Johnstad emphasizes that 'to microdose with a psychedelic drug means to take a dose small enough to provide no intoxication or significant alteration of consciousness' (Johnstad, 2018).

Thus, the term 'microdosing' appears to consist of three components:

1. The use of a low dose below the perceptual threshold that does *not impair* 'normal' functioning of an individual.
2. A procedure that includes multiple dosing sessions.
3. The intention to improve well-being and enhance cognitive and/or emotional processes.

Existing dosing categories for psychedelics when used in research are *very low dose, low dose, medium dose*, and *high dose* (Table 1). A microdose has been defined as approximately one-tenth to one-twentieth of a recreational dose, varying within and between substances, so it can be seen as being somewhat below a very low dose. Although microdosing of psychedelics does not have an agreed scientific definition, we have decided to continue to use the term because of its prevalent societal use. Hopefully, this paper will help to facilitate research towards establishing it as a scientific construct.

The most widely distributed species of psychedelic mushrooms are *Psilocybe cubensis* and those of the genus *Copelandia*, which consists of 12 species (Guzmán *et al.*, 1998). The psilocin (the active metabolite of psilocybin) and psilocybin content in the whole body of these mushrooms when dried was estimated to be in the range of 0.14-0.42% (psilocin) and 0.37-1.30% (psilocybin) for *P. cubensis* and 0.43-0.76% (psilocin) and 0.08-0.22% (psilocybin) for *Copelandia*, respectively. Thus, the former is more psilocybin-rich than the latter, and the latter contains more psilocin compared to the former (Tsujikawa *et al.*, 2003). The *Psilocybe semilanceata* is the most common British species. This mushroom only contains psilocybin, in the range from 0.17 to 1.96%, as shown by one Norwegian analysis (Christiansen *et al.*, 1981; Rumack and Spoerke, 1994). These data show that the psilocybin concentration varies between and within species but is also dependent on the time of collection, the preservation of the material and growth conditions. User reported recreational doses depend on the species and experience of the user (Rumack and Spoerke, 1994).

Table 1. Varying doses of psychedelic compounds used in preclinical and clinical studies.

Substance	Subjects/participants (animal/human)	Route of administration	Microdose	Very low dose	Low dose	Medium dose	High dose
Psilocin (Hasler *et al.*, 2004; Wackermann *et al.*, 2008)	Human (both studies)	Oral	<1 mg	3.15 mg	8 mg	15 mg	22 mg
LSD (Dandiya *et al.*, 1969)	Rats	Intraperitoneally	10-25 µg	30-40 µg	60-110 µg	150 µg	200+ µg
Ibogaine HCl (Glick *et al.*, 2000; Lotsof and Wachtel, 2002; Schechter and Gordon, 1993)[a]	Rats Humans[a]	Intraperitoneally Oral[a]	200 mg	300-400 mg	700 mg	1400 mg[a]	2800 mg
DMT (Shulgin, 1976)	Humans	Intramuscular injection	6 mg	10 mg	20 mg	30 mg	50-70 mg[b]

Per kilogram dose values have been converted to values for a 70-kg person. These doses are approximate values.
[a] Study conducted in humans using a single oral dose of 1400 mg.
[b] When inhaled, 30 mg would be considered a high dose.

A hallucinogenic dose of dried *P. cubensis*, for example, is between 3 and 5 g (Rumack and Spoerke, 1994). These values equate to a recreational dosing range of 8.6 to 14.7 mg of psilocin per dose. Thus, a microdose would range from 0.43 to 0.73 mg of psilocin per dose because a microdose of psilocybin is generally one-tenth of a full dose (Fadiman, 2011). That positions a recreational dose of psilocin between a low and medium dose and a microdose below a very low dose. However, variations in psilocin content between doses of dried mushroom may be seen due to variations between individual fungi within a species. A microdose of LSD ranges between 10 and 20 µg with 20 µg being the upper limit that might already produce perceptual changes in some. A microdose of ibogaine hydrochloride is approximately 25 mg (Kroupa and Wells, 2005), and when smoked, that of *N,N*-dimethyltryptamine (DMT) is approximately 6 mg (May, 2018).

Question 2: What microdosing schedules have been used?

The data presented here were collected using a search of microdosing protocols that included books, online fora and surveys. The keywords of this search included microdosing, microdosing protocols, microdosing approaches and psilocybin microdose. In this search, it was found that users mainly followed three approaches. The most popular of these was the Fadiman approach, outlined in his book (Fadiman, 2011), which involves two consecutive dosing days followed by two non-dosing days. Another popular approach involves 'weekday' dosing, i.e. from Monday to Friday and not dosing on Saturday and Sunday. Additionally, some users indicated that they followed a balanced low/microdose approach, which involved dosing every other day. Dosing periods ranged from 1 week to 2 years. This variation in microdosing schedules was confirmed by a recent survey which demonstrated that half of the respondents who microdosed came up with their own schedule (Hutten *et al.*, 2019).

Question 3: What controlled studies have been done so far?

The first placebo-controlled LSD microdosing study was published recently (Yanakieva *et al.*, 2018). Findings showed a delay of time perception in the absence of self-rated effects on perception, mentation and concentration after administration of single doses of 5, 10, and 20 µg LSD. To our knowledge there has been only one published study designed specifically to measure the effects of psilocybin microdosing per se (Prochazkova *et al.*, 2018) where the effects of psychedelic mushrooms were explored in a recreational setting. This study suffers from a number of methodological issues, particularly the lack of a placebo control as well as uncertainty over dose taken. However, there have been several more controlled studies where a low dose of psilocybin has been used as a control for a regular dose; these are presented below.

For example, Hasler and colleagues (2004) compared four doses of psilocybin in healthy humans in a placebo-controlled experimental design and found slight physiological and psychological differences between single administration of placebo and a very low dose (VLD) (Hasler *et al.*, 2004). A VLD was defined as 45 µg/kg p.o., equating to approximately 2.3 mg of psilocin for an average 70-kg human. VLD was compared with a low dose (LD), a medium dose (MD) and a high dose (HD) defined as 115, 215 and 315 µg/kg p.o., respectively. Although most physiological measures were similar between the VLD dose and placebo, a significant decrease was seen in maximum heart rate at the 6-hour point after VLD administration. Acute self-rated/self-reported psychological responses of VLD included slight drowsiness, increased sensitivity and intensification of pre-existing mood states; an increase in introversion compared to placebo was only shown for the MD and HD at peak drug effect, 95 minutes post-administration.

Building on that, Griffiths and colleagues (2011) investigated the effects of psilocybin in varying doses where each participant received five dosing sessions, spread across 1-month intervals (Griffiths *et al.*, 2011). The doses used were 0, 5, 10, 20 and 30 mg/70 kg. Using a Monitor Rating Questionnaire with a 5-point scale, they found that a dose of 5 mg/70 kg increased stimulation, distance from ordinary reality and sense of peace. Intensity, somaesthesia, affect, perception, cognition and volition measured on the Hallucinogen Rating Scale all increased after administration of a 5 mg/70 kg dose. In other words, they did not find a dose without psychological effects. Interestingly, when using an 11 mg/70 kg and 15 mg/70 kg dose of psilocybin, Lewis and colleagues (2017) found a significant decrease in global cerebral blood flow in the frontal, parietal, temporal, limbic, cingulate and occipital cortex, insula, caudate, putamen, pallidum, amygdala, hippocampus and thalamus (Lewis *et al.*, 2017). This may relate to the psychological effects seen with lower doses.

Psychological effects of microdosing have been regularly reported by users after multiple administrations of psilocybin. Independent accounts from online fora and surveys (Fadiman and Korb, 2019; www.thethirdwave.co; www.dmt-nexus.me, 2018; www.reddit.com, 2018) reveal that users report improvements in energy, mood, cognition, concentration, management of stress, creativity, spiritual awareness, productivity, language capabilities, relationships and visual capabilities. Further, users also reported reduced anxiety, depression and addiction and pain relief. In a recent survey by Anderson and colleagues (2018), users also noted drawbacks such as illegality, stigma, physical discomfort, anxiety, over-stimulation, cognitive interference, emotional difficulty and uncertainty of effect (Anderson *et al.*, 2018). All of these reports are confounded by the lack of certainty relating to the actual dose used, or indeed the provenance of the active ingredient, and the absence of placebo conditions. For a recent review of past research with psychedelic microdosing, please see Passie (2019).

Question 4: Are there any relevant preclinical studies?

We found only two preclinical studies involving microdosing (Cameron *et al.*, 2019; Horsley *et al.*, 2018). Horsley and colleagues (2018) investigated the effect of microdosing on anxiety using an elevated plus-maze and observation of ecological behaviours. They defined a microdose of psilocin as 0.05 mg/kg, which equates to 3.5 mg for an average 70-kg human. Rats received three dosing sessions over 6 days with the last dosing session on the 6th day. Anxiety profiles were measured in Wistar rats 2 days after the final dosing session. Ethological behaviours including rears, head dips and stretch-attend were also measured during this period. Psilocin at 0.05 mg/kg significantly reduced entries into open arms, suggesting that microdosing may have an anxiogenic effect. This effect was not replicated in the ethological measures. Although the authors conclude that these results might have implications for future therapeutic applications, as they produce counter-productive behaviour, one obvious limitation is the interspecies scaling issue (Sharma and McNeill, 2009). It is questionable whether doses administered to animals translate to humans and the authors also acknowledged that the translational value of their results needs to be determined in a therapeutic context.

Cameron and colleagues (2019) tested the effect of repeated low doses of DMT in rats. They gave a dose for 2 months every third day and assessed behaviour with a broad range of tests. In a cued fear extinction learning test, they showed that animals froze significantly less than a control group, suggesting that DMT facilitates fear extinction memory. In the forced swim test, an antidepressant-like effect was observed. No change was observed in dendritic spine density in the layer V pyramidal neurons, and no changes were observed in gene expression (EGR1, EGR2, ARC, FOS, BDNF and 5-HT_{2A}). However, an impact on metabolism was observed in male rats; the weight increased by 182%, compared to 165% with vehicle (Cameron *et al.*, 2019). Comparable to the Horsley *et al.* (2018) study, the interspecies scaling is a point of discussion together with the question of whether a short-acting substance such as DMT would show beneficial effects in humans without administration of a monoamine oxidase (MAO) inhibitor. Lastly, it should be emphasized that there is a need to conduct more research on long-term effects in order to assess the long-term safety of repeat doses.

Question 5: What is the pharmacology of psychedelics when used in microdoses?

The pharmacology of psilocybin and psilocin is still unclear due to the rapid decline in psychedelic drug research following their being made Schedule 1 drugs in 1968 (Rucker *et al.*, 2018). This decline predated the growth of modern neuropharmacology. Thus, more research is required to build a more complete pharmacological profile of psilocybin and psilocin.

Psilocybin (3[2-(dimethylamino)ethyl]indol-4-ol dihydrogen phosphate ester; O-phosphoryl-4-hydroxy-*N*,*N*-dimethyltryptamine) belongs to the indolealkylamine class of psychoactive compounds (Table 2). It is an indole prodrug characterised by a 4-substituent, a phosphate group (Repke *et al.*, 1977), six hydrogen bond acceptors and low lipophilicity (Geiger *et al.*, 2018). Low lipophilicity may contribute to the notion that psilocybin does not cross the blood-brain barrier (Rautio *et al.*, 2008).

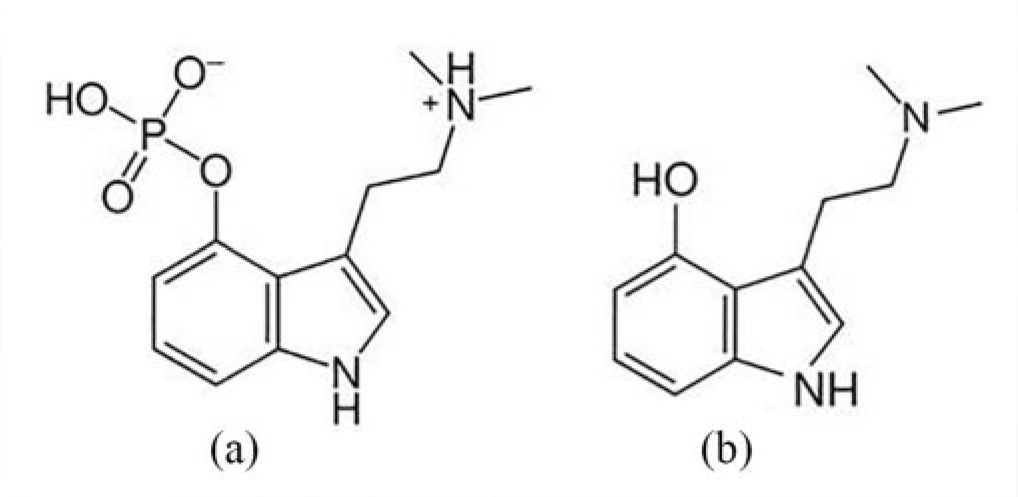

Figure 1. The structure of (a) psilocybin and (b) psilocin.

In vivo, however, the majority of the prodrug psilocybin is rapidly converted to psilocin by alkaline phosphatases present in the blood and tissues. Psilocin has fewer hydrogen bond acceptors in its structure, which increases lipophilicity. In addition, NMR spectral studies have implicated an intramolecular hydrogen bond in psilocin that reduces the basicity of psilocin, increases its lipophilicity and also may render it stable to the action of MAO (Migliaccio *et al.*, 1981). Following systemic circulation, psilocin is metabolized by either phase I or phase II metabolism (Figure 1). The former involves an oxidation reaction to form 4-

hydroxyindole-3-acetaldehyde followed by either an oxidation to 4-hydroxyindole-3-acetic acid or a reduction to 4-hydroxytryptophole. It is believed that none of these metabolites are biologically active. The latter pathway involves the formation of a psilocin *O*-glucuronide conjugate through small intestine and liver enzymes UGT1A10 and UGT1A9, respectively. There is evidence that to some extent, glucuronidated psilocin can be converted back to psilocin (Brown *et al.*, 2017). Although more than 80% of psilocin undergoes phase II metabolism, both phase I and II metabolites are ultimately eliminated through renal excretion.

Depending on body weight, the minimum active oral dose of psilocybin is approximately 4 to 10 mg in humans (van Amsterdam *et al.*, 2011). Onset of action as defined by the first appearance of acute psychological symptoms begins 20 to 60 minutes following oral ingestion and 10 to 40 minutes following buccal administration (Geiger *et al.*, 2018) and almost immediately following i.v. injection (Carhart-Harris *et al.*, 2012).

Psilocin begins to appear in the plasma approximately 25 minutes after oral dosage, with peak levels reached after approximately 105 ± 37 minutes (Brown *et al.*, 2017). A typical user responds to a full active dose for approximately 4 to 7 hours. Even a VLD can produce responses for up to 6 hours after dose administration (Hasler *et al.*, 2004).

Table 2. The physical and chemical properties of psilocybin.

Name	Psilocybin
IUPAC name	3[2-(dimethylamino)ethyl]indol-4-ol dihydrogen phosphate
Other common name	4-Phosphoryl-*N,N*-dimethyltryptamine
Chemical formula	$C_{12}H_{17}N_2O_4P$
Molar mass	204.27 g/mol
Melting point	173 to 176°C (343 to 349°F)
Physical form	Solid
Soluble in	Water Saline

Question 6: Is microdosing safe?

Preclinical studies to assess the safety of repeated doses of psilocybin in rodents have not been conducted. That may be due to several factors, including the historical background of psilocybin as an ingredient in magic mushrooms that had been used in many cultures without apparent harm. Evidence from these accounts demonstrates a lack of serious adverse events resulting from psilocybin administration. There are, however, several non-clinical investigations of psilocybin's safety profile. The risk of an adverse cardiovascular event due to hERG (human ether-a-gogo-related protein) potassium channel blockade is low, with hERG assay results demonstrating minimal effect of psilocybin at concentrations up to 1000 µM (nominal) and completely without effect at 100 µM. That means that unwanted cardiac chronotropic effects with microdosing are very unlikely as the maximum plasma concentration of psilocybin produced by a 25-mg dose would not reach 160 nM (Brown *et al.*, 2017).

Other potential and serious adverse events are cardiac valvulopathies due to repeated activation of serotonin 5-HT_{2B} receptors, which psilocin activates along with many other serotonin receptors. Several drugs have recently been pulled from the market due to this concern. The first example of this was the diet medication Phen/Fen, which had an unacceptably high fatality rate due to its effects on 5-HT_{2B} receptors in the heart (Connolly *et al.*, 1997). Another example is methysergide, an ergot-derived prescription drug that is still being used today as a prophylaxis in difficult to treat migraine and cluster headache (MacGregor and Evers, 2017). It has a known risk of increasing cardiac valve dysfunction (Joseph *et al.*, 2003). In early reports it was shown that although aortic insufficiencies disappeared in most cases after arrest of the methysergide therapy, the mitral insufficiencies remained unchanged (Graham, 1967). It remains to be seen whether repeated low-dose psilocybin administration in preclinical studies might produce valvular hyperplasia, and whether or not this would translate to the human user population. This concern is discussed more in the next section. So far psilocybin testing in preclinical studies has not revealed any signals of valvulopathy.

A different psychedelic that is more often used for microdosing, LSD, has been examined in rodents after repeated dosing schedules similar to microdosing. Comparatively low doses of LSD administered every other day for several months were shown to produce persistent negative behavioural changes that lasted for at least several weeks to months after LSD administration was discontinued (Marona-Lewicka *et al.*, 2011). These changes included increased aggression, scruffy appearance, anhedonia and hyper-reactivity. Analysis of gene expression in key cortical regions like the medial prefrontal cortex indicated that LSD produced alterations in genes enriched for schizophrenia and bipolar depression that lasted long after the drug was discontinued (Martin *et al.*, 2014). Of note, here the interspecies scaling question arises, and it is disputable whether the (low) doses used in animals are comparable to those used by humans (Sharma and McNeill, 2009). Related to these preclinical findings, another primary safety concern for 5-HT$_{2A}$ agonists is the potential for adverse psychological response in humans (Carhart-Harris *et al.*, 2016; Johnston *et al.*, 2010; Vollenweider *et al.*, 1998).

The lethal dose of psilocybin in a single administration in 50% of animals tested (the LD50) ranges from 280 mg/kg in rats and mice to 12.5 mg/kg in rabbits (Usdin and Efron, 1972; Williams, 2013). Animals receiving a very HD of psilocybin (10 mg/kg) exhibit sympathetic system effects such as irregularities in heart and breathing rate as well as mydriasis, piloerection, hyperglycaemia and hypertonia (Cerletti, 1958). Similar central excitatory effects were seen after the administration of 2-4 mg/kg intraperitoneal psilocybin in rhesus monkeys (Horibe, 1974).

Question 7: What receptors will be involved in the activity of microdosed psilocybin?

Psilocin predominantly binds to serotonin receptors: 5-HT$_{1A}$, 5-HT$_{1D}$, 5-HT$_{1E}$, 5-HT$_{2A}$, 5-HT$_{2B}$, 5-HT$_{2C}$, 5-HT$_{5}$, 5-HT$_{6}$ and 5-HT$_{7}$ (Table 3) (McKenna *et al.*, 1990) and the serotonin transporter and partially to the norepinephrine transporter, similar to MDMA (Rickli *et al.*, 2016). Hill slope values demonstrate that psilocin binds independently at all 5-HT receptors except 5-HT$_{2B}$ where cooperative binding is exhibited (McKenna *et al.*, 1990).

Cerebral 5-HT receptors that can be stimulated by psilocin are highly distributed among different regions (Table 3). Many behavioural and neuropsychological effects claimed to be elicited by microdosing are known to be modulated by these receptors (Anderson *et al.*, 2018).

Psilocin acts as a partial agonist at the 5-HT$_{2A}$ receptor with 46% (+/-2.4) response compared with the response produced by serotonin for signalling through the phospholipase C (PLC) pathway (Kurrasch-Orbaugh *et al.*, 2003). It has a lower binding affinity to the 5-HT$_{2A}$ receptor compared to LSD (Rickli *et al.*, 2016). Currently there is only one study of the in vivo cerebral 5-HT$_{2A}$ receptor occupancy produced by the psilocybin metabolite psilocin in humans. That was done by the Copenhagen group led by Knudsen who used the PET tracer [11C]Cimbi-36. This tracer is an agonist of the 5-HT$_{2A}$ receptor and therefore particularly sensitive to displacement by another agonist, psilocin. Having performed a dose-finding study of psilocybin that ranged from 3 to 30 mg p.o. per person, they found that the plasma concentration that produced a 50% occupancy of the 5-HT$_{2A}$ receptor was 1.95 (range 1.16-3.15) µg psilocin/L (Madsen *et al.*, 2019). They also found that plasma psilocin was positively correlated with subjective intensity ratings and that doses producing less than 20% occupancy (i.e. probably less than 0.028 mg/kg body weight) were not detectable either by psychological or physiological measurements (Madsen *et al.*, 2019), suggesting that this concentration might represent the threshold for microdosing, based on brain 5-HT$_{2A}$ receptor occupancy.

Receptor type	G-protein	Distribution	Physiological response	Behavioural response	Agonist	Antagonist	Drug classes that act on this receptor	Psilocin binding affinity: Ki (nM) (Halberstadt and Geyer, 2011)
5-HT$_{1A}$	Gi	Cerebral cortex, hippocampus, septum, amygdala and raphe nucleus in high densities. Low amounts also exist in the basal ganglia and thalamus (Beliveau *et al.*, 2017)	I. Hypotension II. Increase DA release in the medial prefrontal cortex, striatum and hippocampus	I. Decreased anxiety and depression (Campos and Guimarães, 2008) II. Impairment of declarative and non-declarative memory III. Decreased aggression and impulsivity IV. Inhibition of drug-seeking behaviour	8-OH DPAT, buspirone, 5-CT (Barnes and Sharp, 1999), psilocybin (Mckenna *et al.*, 1990)	WAY 100135 (methiothepin nonselective) (Barnes and Sharp, 1999)	I Analgesics (agonists) II Antidepressants (postsynaptic receptor agonists and pre-synaptic autoreceptor antagonists) III Anxiolytics (antagonists)	567.4
5-HT$_{1D}$	Gi	Trigeminal sensory neurones including peripheral and central projections to dural blood vessels and to the medulla (Longmore *et al.*, 1997)	Inhibition of adenylyl cyclase	I. Modulates locomotion and anxiety II. Migraine prophylaxis (Longmore *et al.*, 1997)	Dextromethorphan, sumatriptan, L694247, 5-CT (Barnes and Sharp, 1999), psilocybin (McKenna *et al.*, 1990)	Sumatriptan, GR 127935 (metergoline, methiothepin nonselective) (Barnes and Sharp, 1999)	I. Triptans (agonists used for migraine)	36.4
5-HT$_{1E}$	Gi	High levels in olfactory bulb glomeruli and molecular layer of dentate gyrus. Low amounts in the adventitial layer of cerebral arteries (Klein and Teitler, 2012)	Inhibition of adenylyl cyclase		5-HT (Barnes and Sharp, 1999), psilocybin (McKenna *et al.*, 1990)	None (methiothepin weak) (Barnes and Sharp, 1999)		N/A
5-HT$_{2A}$	Gq/11	High concentrations on the apical dendrites of pyramidal cells in layer V, neocortex (mainly prefrontal, parietal and somatosensory cortex) and the olfactory tubercle, as well as cardiovascular system (Beliveau *et al.*, 2017)	I. Vasoconstriction II. Platelet aggregation III. Bronchoconstriction IV. Anti-inflammatory	I. Modulates addiction II. Increased anxiety III. Increased appetite IV. Improved cognition (learning and memory) V. Decreased sleep VI. Modulates sexual behaviour	Alpha-methyl-5-HT, DOI (Barnes and Sharp, 1999), psilocybin (McKenna *et al.*, 1990)	Ketanserin, pimvanserin, pirenperone (Barnes and Sharp, 1999)	I. Atypical antipsychotics (antagonists) II. Antidepressants and anxiolytics (antagonists)	107.2

5-HT$_{2B}$	Gq/11	Predominantly peripheral, widespread tissue distribution including liver and kidneys (Julius *et al.*, 1990)	Vasoconstriction	I. Regulates sleep (Qian *et al.*, 2017) II. Increased GI motility, especially small intestine III. Increased cardiac hypertrophy in mice	Alpha-methyl-5-HT, DOI (Barnes and Sharp, 1999), psilocybin (Mckenna *et al.*, 1990)	SB 200646 (also 5-HT$_{2C}$ antagonist)		4.6
5-HT$_{2C}$	Gq/11	Mainly in choroid plexus, high concentrations in hippocampus, anterior olfactory nucleus, substantia nigra, amygdala, subthalamic nucleus and lateral habenula (Julius *et al.*, 1990)	I. Vasoconstriction II. Increase phosphoinositide turnover	I. Increased anxiety II. Increased GI motility III. Modulates locomotion IV. Modulates mood and sexual behaviour	Alpha-methyl-5-HT, DOI, psilocybin (McKenna *et al.*, 1990)	Mesulergine (also 5-HT$_{2A}$ antagonist)	I. Antidepressant (antagonists) II. Orexigenic (antagonists) III. Anorectic (agonists) IV. Antipsychotic (agonists)	97.3
5-HT$_{5A}$	Gi/Go	High concentrations in olfactory bulb and medial habenula of wild-type mice. Lower densities in neocortex, hippocampus and trigeminal nucleus	N/A	I. Modulates locomotion II. Increases sleep	5-CT, valerenic acid (partial agonist)	Methiothepin, ritanserin, asenapine, psilocybin (McKenna *et al.*, 1990)	N/A	83.7
5-HT$_6$	Gs	Predominantly in the caudate nucleus, with lower concentrations in hippocampus and amygdala. Very low levels of expression in the thalamus, subthalamic nucleus and substantial nigra (Yoshioka *et al.*, 1998)	Activation of adenylyl cyclase (HEK 293 cells)	I. Increased anxiety II. Reduced cognition and memory III. Negative effect on mood	EDMT, EMD-386,088	Amitriptyline aripiprazole, MS-245, psilocybin (McKenna *et al.*, 1990)	I. Antidepressants (antagonists) II. Anxiolytics (antagonists) III. Nootropics (antagonists) IV. Anorectics (antagonists)	57.0
5-HT$_7$	Gs	Predominantly the caudate and putamen nuclei, the pyramidal layer of the CA2 field of the hippocampus, the centromedial thalamic nucleus and the dorsal raphe nucleus (Ruat *et al.*, 1993)	I. Activation of adenylyl cyclase (HeLa cells and COS cells) II. Vasoconstriction	I. Increased anxiety II. Decreased mood III. Reduced working and reference memory	5-CT, 8-OH-DPAT, aripiprazole, AS-19, psilocybin (Glennon, 2003)	Methiothepin, mianserin, SB-269,270	I. Antidepressants (antagonists) II. Anxiolytics (antagonists) III. Nootropics (antagonists)	3.5

At this dose level, several 5-HT receptors other than the 5-HT_{2A} receptor may also be affected. This could include antagonist activity at the 5-HT_6 and 5-HT_7 receptors that may improve mood and cognition (Ballaz *et al*., 2007; Mnie-Filali *et al*., 2009). The 5-HT_7 receptor is also implicated in the regulation of circadian rhythms (Lovenberg *et al*., 1993). Upon assessing binding affinity of LSD and DMT at 5-HT_7 receptors, similarly high Ki values of 9.5 nM (Ruat *et al*., 1993) were found. Additionally, it has been found that 5-HT_7 receptor activation reduces secondary hypersensitization in response to capsaicin in mice (Brenchat *et al*., 2009). Thus, psilocybin agonist activity at 5-HT_7 may relate to the ancient use of '*teonanácatl*' to ease rheumatism.

Further, psilocin also binds with relatively high affinities to 5-HT_{1D} (K_i = 36.4 nM) and 5-HT_{2B} (K_i = 4.6 nM) receptors. 5-HT_{1D} is predominantly expressed in the trigeminal system, which may account for the recent reports of self-medication using microdoses of psychedelics to produce migraine prophylaxis (May, 2018). With regard to the 5-HT_{2B} there are concerns of the development of cardiac valvulopathy associated with agonism at 5-HT_{2B} (Elangbam *et al*., 2005). It is mostly the use of intermittent highdose psilocybin intake that has been discredited. However, even with repeated microdosing there is a possibility that 5-HT_{2B} receptors might be stimulated enough to lead to tissue overgrowth. A potential mitigation against this risk is the suggestion that the efficacy of psilocin (EC50 > 20 µM) (May, 2018) is lower than that of 5-HT. Nonetheless, because psilocin also has a higher affinity for the 5-HT_{2B} receptor than 5-HT, further investigation is needed to understand better the risks associated with microdosing.

Some stimulation at 5-HT_{1A} receptors may also occur. Such activity has been implicated in the mechanism of action of antidepressant medications including SSRIs (Celeda *et al*., 2013). Activation of these receptors by psilocin could conceivably be involved in reduction in anxiety and increased mood swings (Carhart-Harris and Nutt, 2017) due to dense distribution of the receptor in the midbrain, limbic and cortical regions that regulate stress and emotion.

Question 8: Are the claims of the benefits of microdosing biologically plausible?

There have been only a few studies on the basic neurobiology of psychedelics at the 5-HT_{2A} receptor. Recent work has shown that psychedelics like DOI and LSD directly produce transcriptional activation of Immediate Early Genes (IEGs) like *cfos* in only about 5% of neurons within key brain structures, and that these activated Trigger Population neurons express significantly higher levels of receptor than the non-activated neurons (Martin and Nichols, 2016). Transcriptional activation of IEGs within neurons is generally accepted to be a reliable marker for neural activity (Joo *et al*., 2016). Further, psychedelics also act on subsets of inhibitory neurons, and non-neuronal cells like glia and astrocytes (Martin and Nichols, 2016). Together, these data indicate that within specific brain regions, psychedelics trigger complex patterns of excitatory and inhibitory neurons in small subsets of cells, and that how these cells are activated differs between brain regions (Martin and Nichols, 2016).

Genes acutely activated by LSD in the brain are predominantly involved in synaptic plasticity (Nichols and Sanders-Bush, 2002; Nichols and Sanders-Bush, 2004). Accordingly, activation of 5-HT_{2A} receptors in brain slice culture modulates aspects of long-term plasticity, and expression of brain-derived neurotrophic factor (BDNF) (Vollenweider and Kometer, 2010). BDNF expression is also observed to increase in primary cultures of cortical neurons 24 hours following the application of psychedelics (DOI, DMT, LSD) (Ly *et al*., 2018). Blockade of the receptor for BDNF, Trk-B, prevents increased spinogenesis and synaptogenesis in cortical neurons that have been treated with psychedelics. Interestingly, the mammalian target of the rapamycin (mTOR) pathway is activated downstream of psychedelics in cortical neuron cultures similarly to ketamine, and likely mechanistically underlies the synaptogenesis (Ly *et al*., 2018). None of these preclinical studies, however, utilized psilocybin, and it remains to be seen if it produces the same effects, and if so, at what dose?

Psychedelics are known to induce behavioural tolerance, an absence of behavioural effects after repeated intake of a substance. Previously it was shown that behavioural effects were for example diminished after repeated doses of LSD (Abramson *et al*., 1956); in addition, another study showed these effects to be associated with reduced cortical 5-HT_{2A} receptor binding (Gresch *et al*., 2005). Serotonin syndrome-related symptoms, skin jerks, shaking behaviour and hyperthermia, induced by a single dose of the 5-HT_{2A} agonist DOI in rats were absent after repeated low dosing, suggesting behavioural tolerance (Pranzatelli and Pluchino, 1991). Although speculative, this downregulation of the 5-HT_{2A} receptor might be a mechanism of action underlying some of its putative therapeutic effects. An example is obsessive-compulsive disorder (OCD), a psychiatric condition that is characterized by increased 5-HT_{2A} binding (Adams *et al.*, 2005). Preliminary data have shown that administration of low to high doses of psilocybin lead to symptom reduction in patients with OCD (Moreno *et al.*, 2006). It was previously suggested that a re-balance between 5-HT_{1A} and 5-HT_{2A} receptors might be responsible for observed therapeutic actions (Buchborn *et al.*, 2014), but this remains to be investigated.

In peripheral tissues, very low doses of psychedelics have profound anti-inflammatory effects (Yu *et al.*, 2008). In general, psychedelics in the phenethylamine class such as DOI have more potency than those in the ergoline class such as LSD. In a rodent model of asthma, for example, levels of the R stereoisomer (*R*)-DOI that are 30 times lower than the behavioural threshold can have profound effects to prevent inflammation, T-Helper Cell Type 2 (Th2) cell recruitment, eosinophilia and mucus production in the lung, resulting in animals that can breathe normally after exposure to an allergen (Nau *et al.*, 2015). In another animal model of inflammatory bowel disease, levels of the psychedelic (R)-DOI 30 times lower than the behavioural threshold nearly completely prevented intestinal inflammation (Nau *et al.*, 2013). It remains to be seen whether very low levels of psychedelics are also anti-inflammatory in humans, and if the anti-inflammatory activity also occurs in the brain, but if these findings do translate then levels typically used in microdosing regimes for some psychedelic compounds would be predicted to have significant and beneficial anti-inflammatory effects. Interestingly, although LSD is one of the most powerful and potent mind-altering psychedelics, it is comparatively among the least potent anti-inflammatories tested (Yu *et al.*, 2008).

Question 9: What is the legal position of microdosing?

The answer to this question is complex due to differences in national regulations. In general, under the UN Conventions, LSD and related compounds, psilocybin and DMT are controlled as Schedule 1 drugs - i.e. are defined as being the most harmful and as having no medicinal value. In other words, they are subject to the most extreme restrictions and penalties for unapproved possession. These constraints apply to any dose of the drug, even a sub-psychoactive or microdose level. Research can be carried out with the right ethical regulatory and institutional approvals, but dosing would have to be conducted in a secure environment like a hospital or research ward. For repeated microdosing, this adds significant costs and complexity to any study, which is likely why none have yet been reported.

However, this situation is easing for psilocybin as a result of several successful clinical trials in recent years, and both the European and US regulators have given approval for studies (NIH, 2018) with psychedelic doses of synthetic psilocybin made to GMP standards. That means that microdosing trials of similarly sourced product for clinical therapy are likely also to be approved, though as yet we do not believe any have been submitted.

Question 10: What are the regulatory issues?

Unfortunately, due to their long history of anecdotal use in recreational settings, none of the psychedelics has ever followed the conventional drug research and development path expected by contemporary standards. Thus, at best, doses have been selected based on published data in a variety of indications but mostly to provide an indication for an upper safety limit. In a pooled analysis of psilocybin Studerus *et al*. (2011) classified active oral doses within a vast range of about one order of magnitude difference, between 0.045 and 0.315 mg/kg, which translates into 3.15 to 22.05 mg for a 70-kg human (Studerus *et al*., 2011). Such a range is quite surprising for active principles with the pharmacological potency of psychedelics. Given such underdetermination, regulatory standards will most likely require dedicated dose-finding studies (more than one) to provide a rationale explaining the known individual differences that have been reported in the clinical response to treatment and most importantly, the dose chosen for late development. In this context, the information provided from oral dosing, resulting plasma psilocin levels and corresponding brain 5-HT_{2A} receptor occupancy will turn out to be informative.

Parallel fixed dose designs are usually recommended (ICH, 1994). In some cases, four arm range studies could be necessary; under these circumstances microdoses could be used to test pseudo-placebo properties or alternatively a peculiar pharmacological activity.

Another issue pertains to the limited pharmacokinetic data available in order to evaluate a dose-concentration-response relationship for psychedelics. Updated ADME studies are not available for psychedelics, although the characterization of their metabolites and their role in the active principle efficacy or safety profile might prove relevant to interpret and predict their clinical effect. Once pharmacokinetics of the parent compound and its metabolite(s) are established, variation of clearance if any, its prediction by body weight and the concentration-response relationship for the claimed clinical effect must be presented. If possible, biomarker(s) (e.g. single-nucleotide polymorphisms (SNPs)) at the 5-HT receptor subtypes where they have affinity should be linked to the risk/benefit profile and thus to the therapeutic effect, and they could be used to enrich/ stratify the population of interest. Because psychedelics have been reported by some to possess a large inter-individual sensitivity, the definition of a precise concentration-response relationship may be difficult to demonstrate, especially once a microdose range is reached.

Question 11: What are the future research needs?

Microdosing is generally accepted as the use of a functionally low dose of a psychedelic compound over multiple dosing sessions with the intention of improving mental and physical well-being, cognition or creativity (Fadiman, 2011; Johnstad, 2018). A systematic study of microdosing psychedelics investigated by means of observation changes in psychological variables of microdosers. Small changes in a sub-set of variables were found, i.e. decreased depression and stress, decreased mind wandering, increased absorption and increased neuroticism. Interestingly, these variables were not those that participants most expected to change, suggesting that long-term changes may be due to biological changes and not only expectations (Polito and Stevenson, 2019). Nonetheless, the possible effects and implications of microdosing remain largely unknown. Although there is a large database of reported effects of 'microdosing' on online fora, the true amount of active substance in these is unknown as are the peak plasma psilocin concentrations achieved during 'intoxication'. Further, while in these anecdotal reports the user deliberately ingests a substance for a reason, expecting positive effects, it is difficult to distinguish between expectation 'placebo' effects and the effect of a microdose. These non-pharmacological effects, described as set and setting, are also known to be of influence when taking a full dose of a psychedelic (Hartogsohn, 2017). Another unknown is whether effects are noticeable after only one microdose or that a certain 'build-up' is needed, supported by underlying neurobiological changes, before effects occur.

Therefore, rigorous placebo-controlled clinical studies need to be conducted with different low doses of the drug to determine whether there is any evidence for the claims being made by microdosers. The types of cognitive testing performed should include several different validated psychological instruments and preferably cover the concepts mentioned in the Research Domain Criteria (Cuthbert and Kozak, 2013), and not simply rely on anecdotal accounts or simple tests. Generated knowledge in healthy volunteers will provide clear information on which cognitive aspects can be enhanced with microdosing. This knowledge will provide a first hint as to whether microdosing can be of value in the treatment of specific symptoms in psychiatric populations. Anecdotal reports suggest, for example, that microdosing might help in combatting attention deficit hyperactivity disorder (ADHD) symptoms; studies including measures related to symptom domains like executive functioning, attention and temporal processing will help to decode the potential of microdosing as a therapeutic agent. In terms of biological mechanism of action, more (pre)clinical work needs to be performed to understand fully the complex interaction of different cell types, and their responses to psychedelics at the molecular level such as elucidating peripheral or central signalling pathways involved, if any, in the process of microdosing (Kuypers, 2019). Resulting findings can provide theoretical grounds for why microdosing could work in alleviating cluster headache in patients suffering from it (Anderson *et al*., 2018; Johnstad, 2018).

Whereas most anecdotal reports focus on the positive experiences with microdosing, future research should investigate the molecular mechanisms behind low-dose psilocybin behavioural effects as well as address potential risks of (multiple) administrations of a psychedelic in low doses. Although extensive toxicology has been conducted on a single active dose of psilocybin and has been proven to be safe (Brown *et al*., 2017; Johnson *et al*., 2018), further research is required to understand better the possible health risks incurred by microdosing, especially in relation to cardiac and lung tissue. These studies would involve (pre)clinical safety and tolerability tests of multiple low/microdoses of psilocybin over an extended period of time. To that end, continuous monitoring of physiological parameters including heart functioning in addition to assessment of receptor turnover at low/microdoses as well as receptor occupancy will shed light on the potential negative consequences microdosing could have.

Microdosing psychedelics: Too much hype, almost no rigorous research

A call to explore microdosing's psychological effects and therapeutic potential within psychiatry

by **Stephen Ross**

This timely article ('Microdosing psychedelics: More questions than answers? An overview and suggestions for future research') provides an excellent overview on the topic of microdosing psychedelics. The review focuses predominantly on psilocybin with some mention of other psychedelics (i.e. LSD, ibogaine and DMT). This article is organized around a series of questions and answers that includes the following topics related to microdosing: basic definitions, varying dosing regimens, relevant preclinical data, pharmacology, safety issues, potential biological mechanisms of action, scientific evidence base (or relative lack thereof) from published peer-reviewed research, legal and regulatory issues, and a call for rigorous placebo-controlled trials to test the various beneficial claims of microdosing made so far by anecdotal reports.

The therapeutic application of the classical psychedelics within psychiatry has made a historic come back within the last two decades and is at inflection point with a growing body of rigorously conducted research pointing to the promising clinical utility of psychedelic-assisted psychotherapies to treat a range of psychiatric disorders, with the data most robust for: cancer-related psychological and existential distress (Gasser *et al.*, 2014; Griffiths *et al.*, 2016; Grob *et al.*, 2011; Ross *et al.*, 2016), alcohol and tobacco addiction (Bogenschutz *et al.*, 2015; Johnson *et al.*, 2014), and major depression (Carhart-Harris *et al.*, 2016; Osorio *et al.*, 2015). The doses used in all of these clinical trials are of the 'macro' variety, typically consisting of moderate to high-dose psilocybin, administered as part of the psychedelic therapy model in combination with psychotherapy with the goal of inducing significant alterations of consciousness, including mystico-mimetic states (Bogenschutz and Ross, 2018).

In contrast, and as defined in this article, microdosing is a practice of consuming very low doses of a psychedelic substance (that produce acute drug effects that are either not perceptible or minimally identifiable), utilizing a repeated dosing regimen, and with the goal of improving well-being, enhancing productivity or increasing creativity. It is distinct from both psychedelic therapy (i.e. using high doses of psychedelics to occasion mystical-type experiences, and used historically to treat conditions such as alcoholism and terminal cancer-related existential distress) and psycholytic therapy (i.e. using lower doses of psychedelics to produce perceptible and significant shifts in cognition and affect to enhance psychotherapy, historically used in combination with psychoanalytic psychotherapy to treat various psychiatric conditions such as anxiety spectrum disorders) (Ross and Bogenschutz, 2017). Structured microdosing regimens employed so far (typically by lay individuals with the intention of receiving some positive benefit) range from daily use to dosing every 3 days (Fadiman, 2011), and occurring over varying time-frames from monthly to ongoing. Microdosing has surged in popularity over the last several years and has been associated with the use of serotoninergic psychedelics (i.e. LSD, psilocybin, ayahuasca, iboga), cannabinoids (i.e. CBD), and dissociative anaesthetics (i.e. ketamine) (Kitchens, 2018). Even though microdosing does not cause significant alterations in perception with acute administration, it has led to numerous anecdotal reports (featured in a rapidly growing number of media articles) of claimed benefits in a variety of domains including: Psychological (i.e. improved mood, energy, emotional balance, empathy, openness, introspection; decreased pain and alcohol/drug use or craving); Cognitive (i.e. improved focus, concentration, mental clarity); Creativity (i.e. improved idea generation and divergent thought processes); Spirituality (i.e. improved meaning in life); Interpersonal (i.e. improved connectedness, sensitivity to others, relational skills); and General well-being and quality of life (i.e. improved sleep quality, healthy eating habits, sexual function) (Austin, 2016; Kitchens, 2018).

Despite all of the growing interest and purported claims of benefits of microdosing, basic knowledge about microdosing, including therapeutic effects, is virtually absent due to almost no peer-reviewed publications stemming from rigorously conducted research. Some of the most significant and important gaps in the knowledge base of microdosing include the absence or paucity of: rigorous design methodology including randomization, placebo control, adequate blinding integrity, and the use of appropriate inclusion/exclusion criteria to minimize potential harm; prior approval with appropriate ethical and human subjects review boards; the use of and dispensation of an exact known dose of pharmaceutical grade psychedelic in a controlled setting; understanding basic effects on psychological, cognitive and affective domains; adequate safety monitoring and knowledge of acute or long-term safety issues; understanding of basic neurobiological or potential mechanisms of action, such as neuroimaging (i.e. PET, functional MRI), physiological data (i.e. EEG, MEG) and biomarkers (i.e. BDNF).

This article touches on most of these gaps. The review article points out that there has only been one published trial that specifically examined the effects of psilocybin microdosing. This was an open-label, non-controlled trial, with uncertain doses of psilocybin ingested, that was conducted without ethical approval. It reported on improvements in two creativity-related problem-solving tasks following recreational psilocybin microdosing (Prochazkova *et al*., 2018). A limitation of the present article is the focus on psilocybin even though online fora suggest that recreational LSD microdosing may be as common (if not more so) than psilocybin microdosing (www.reddit.com, 2019). By not focusing equally on LSD microdosing, the article does not capture the most rigorously conducted and peer-reviewed published trial of microdosing to date. Unlike all of the prior publications on microdosing, this trial was approved by an independent ethics committee, included random assignment, double-blind methodology, and the use of a placebo condition (Yanakieva, 2018). Further, appropriate inclusion/exclusion criteria were used to enhance safety, the trial was conducted in a monitored inpatient setting to optimize safety and exact doses of pharmaceutical grade cGMP LSD were administered. In comparing three microdoses of LSD (5, 10 and 20 µg) to placebo, the trial reported that LSD microdosing produced temporal dilation in the absence of significant consciousness alteration (Yanakieva *et al*., 2018).

The review article also focuses on some theoretical safety concerns such as the link between 5-HT$_{2B}$ agonism and cardiac valvulopathies (Cavera and Guillon, 2014). The article would have been strengthened by a call to monitor broadly for potential adverse medical and psychiatric effects in future microdosing research to be able to identify all of the unknown risks that may be associated with microdosing. For example, we do not know the risks associated with the interaction between microdosing and underlying psychiatric illnesses. All of the modern therapeutic trials of psychedelic-assisted psychotherapies exclude participants with psychotic spectrum illnesses because of the known negative association between psychedelic use and psychotic exacerbation in those with underlying psychotic illness (Ross and Peselow, 2012). In the early stages of microdosing research, it would be important to begin cautiously by excluding individuals with significant psychiatric, medical or neurological illnesses.

One area not covered by the review article is speculation on the potential therapeutic utility of microdosing within psychiatry. If some of the claimed psychological or cognitive benefits (i.e. improved mood and attention; decreased substance craving and pain perception) of microdosing are real (i.e. not simply due to placebo or expectancy effects), the next logical step would be to test the potential efficacy of microdosing in various clinical populations (i.e. major depression, bipolar depression, ADHD, addictive disorders, pain disorders) through RCTs, and beyond through the drug development process. Funding sources would have to be considered, whether that would come through private philanthropy, pharma or governmental funding agencies (i.e. NIHR in Europe or NIH in the USA). Finally, if microdosing proves to be effective for the many claimed effects reported in the lay public (i.e. enhanced creativity, work productivity, learning, memory, empathy, connection to others, spirituality), it could potentially be used to improve function in 'normals' without specific disease states, although it is unclear how drug development would proceed for non-clinical entities by using mostly illegal substances.

Psychedelics: What are low doses and "microdoses"?

by **Matthias E Liechti**

Keywords LSD, microdosing, dosing, pharmacokinetics, psilocybin, psychedelics

In clinical pharmacology, 'microdosing' refers to the use of a dose of a substance with <1% pharmacological activity to study pharmacokinetics (PK), including absorption, distribution, metabolism and excretion, potentially using non-good-manufacturing practice (GMP) material and/or radio-labelled substances (e.g. Muehlan *et al.*, 2018). 'Microdosing' with lysergic acid diethylamide (LSD) or psilocybin refers to the use of low to very low doses (i.e. 5-20% of fully active doses; Table 1). I would rather label such use as 'low to very low doses'.

While I mostly agree with the views in the article, I would like to add some additional thoughts on dosing with a focus on LSD. What is actually meant by the micrograms of LSD doses? Correct doses are obviously unknown in the case of illicit sources, and the correct reporting of doses is also an issue in scientific publications. Research in the 1950s to 1970s used LSD tartrate, whereas modern research commonly uses LSD base (Liechti, 2017), with the exception of at least one study (Yanakieva *et al.*, 2018). A dose of 100 µg LSD base corresponds to 123 µg LSD tartrate (when being free of crystal water or methanol solvate; Mesley and Evans, 1969) - this dose may not be considered low (Table 1). Thus, researchers need to indicate whether they are reporting base or salt doses. Additionally, LSD is mostly not a pharmaceutical product and not manufactured according to GMP with defined content and stability. Researchers produce their own formulations. It is often not reported where the substance was obtained from and the way in which it was formulated as the final study drug. This raises many questions. Are the reported doses salt or base? What is the purity? What is the content of crystal water, solvate and/or residual solvents? How was this factored into the reported dose? What is the content uniformity and stability of the product throughout the study duration? What is the amount of inactive iso-LSD in the pharmaceutical formulation?

LSD is inactivated to iso-LSD depending on temperature, solvent and pH and thus may be unstable in certain formulations. Other stress factors such as light, oxygen or tap water chlorine may also lead to decomposition of the LSD molecule. In fact, amounts of iso-LSD were detected in plasma in research subjects, indicating that approximately 30% of the LSD that was administered likely isomerized to inactive iso-LSD possibly within the LSD capsules that were used (Steuer *et al.*, 2017). Novel PK studies (Holze *et al*. 2019) that use validly defined doses of a novel LSD formulation indicate that previous studies used 70 and 140 µg of LSD base (equivalent to 86 and 172 µg LSD tartrate) rather than the reported oral doses of 100 and 200 µg LSD base (Dolder *et al.*, 2017; Liechti, 2017; Preller *et al.*, 2017). In addition to correctly assessing and reporting the study drug, PK data are needed, thus providing the basis of the present discussion and any drug development. Plasma concentrations provide an objective measure of the substance that actually arrives in the body by accounting for dosing, bioavailability and inter-individual differences in absorption, distribution, metabolism and excretion. Plasma concentrations are also needed to compare formulations and substance exposures between different studies and different research groups and should be generated for each novel formulation.

With regard to 'microdosing with LSD', researchers cannot unequivocally conclude that 5-20 µg LSD base has no acute subjective effects or does not impair normal functioning as noted in the definition of 'microdosing'. I would argue that these doses can produce similar acute subjective effects but to a lesser degree compared with clearly psychoactive doses (> 25 µg LSD base). A recent placebo-controlled study that used single doses of 5-20 µg LSD tartrate (GMP-formulated, 4-16 µg LSD base) reported statistically significant acute subjective drug effects (Yanakieva *et al.*, 2018). Studies that used PK-pharmacodynamic modelling (Dolder *et al.*, 2015, 2017; Holze *et al.*, 2019) allow the evaluation of plasma concentration/dose-effect relationships of LSD in humans, in which subjective effects parallel plasma LSD concentration-time curves. Plasma concentrations of LSD at the EC_{50} for 'good subjective drug ratings' are very low (1 ng/ mL). Subjective mean good drug effects of 25% of these full doses have been reported at an average plasma LSD concentration of 0.4 ng/mL (Dolder *et al*., 2017; Holze *et al*., 2019). The C_{max} after 100 µg LSD base administration was 1.7 ng/mL (Holze *et al*., 2019). Based on the linear PK of LSD, C_{max} values of 0.4 ng/mL are likely reached with a 25-µg dose. Based on the available data and ongoing studies, base doses of LSD of 25, 10 or 5 µg can be postulated to produce approximately 25%, 10% and 5%, respectively, of the effects of a fully active dose of 100 µg LSD base. Additionally, there is no indication that the acute subjective effects of these very low to low doses of LSD are qualitatively different from a full dose. Thus, there is no apparent evidence that LSD, which impairs cognition at active doses, would magically enhance concentration when used at lower doses as described by users. In fact, decreases in self-reported concentration and task-measured cognitive performance have been reported at high and low plasma LSD concentrations (Dolder *et al*., 2016; Schmid *et al*., 2015). Very low to low doses of 5-20 µg LSD tartrate ('microdoses') did not significantly alter self-ratings of perceptual distortion or subjective concentration, but trends towards impairments were observed (Yanakieva *et al*., 2018). These effects would likely become significant in well-powered studies with larger sample sizes.

This raises another important issue. Very low doses of substances will produce very small effects. To validly assess small treatment effects, study sample sizes need to be larger than those that are common in experimental psychiatric research. Additionally, sensitive measures need to be used. Many validated psychiatric scales may not be sufficiently sensitive to detect small drug effects, and simple drug-effect visual analogue scale ratings are likely better. Furthermore, vital signs could serve as a simple objective measure of reactivity. However, psychiatric studies typically have shortcomings with regard to performing vital sign assessments. For example, very low to low doses of psilocybin did not alter blood pressure in one study (Hasler *et al*., 2004). However, for this finding to be valid, vital signs need to be assessed according to standard operating procedures. This includes the use of scaled instruments, exactly determined time points after drug administration, time-matched placebo control measures and so on. For example, a safety and efficacy study reported that LSD did not significantly alter blood pressure or heart rate at a dose of 200 µg LSD (Gasser *et al*., 2014). However, this same dose and lower doses were subsequently shown to significantly and relevantly increase blood pressure, heart rate, body temperature and pupil size in studies that used standardized measures (Schmid *et al*., 2015; Dolder *et al*., 2016).

Altogether, we are still in the incipient stage of modern research on psychedelics. Even for relatively high doses of these substances, the data are still scant and inconsistent. Thus, it is too early to make valid conclusions about the effects of very low doses of these substances. Currently (Passie, 2019), I see no valid data that indicate that LSD or psilocybin has either beneficial or adverse effects on health when used repeatedly at low to very low doses (Passie, 2019). This simply needs to be studied further.

As microdoses are being used worldwide, this is a timely article. Prudently, the authors have focused on synthesized psilocybin, as it may soon become more available. As our own research has been entirely anecdotal, and although it includes reports from 51 countries and thousands of individuals, it does not answer any of the questions raised here. What our exploratory findings may have done is help raise the level of interest about the reported negative or positive effects and mechanisms of action. While we have added suggestions and noted a few concerns here, the investigations proposed in the article are all necessary and fundamental.

Early on, it could be important to determine if the same weight of psilocybin in a mushroom with its other alkaloids (found in over 100 mushroom species) has a similar behavioural profile to the synthetic. Equally useful, and perhaps eventually as necessary, would be to replicate the same study with LSD-25 and 1P-LSD. The reason for suggesting these equivalence studies is that of the several hundred thousand people known to have microdosed, less than 1% of them actually used the GMP grade psilocybin. If their experiences differ from those using the synthetic substance, a great deal of otherwise correlative data would need to be put aside.

It seems to us that the worry about cardiac valvulopathy is excessive, given the overall safety profiles of all of the classic psychedelics described in several of Dr. Nutt's publications.

The Fen-Phen experiences of heart valve disease development in the 1980s and 1990s inspired new research in identifying the specific 5-HT receptor subtype involved in drug-induced heart valve disease. In the cases of cardiotoxicity and Fen-Phen, both 5-HTP2A and 5-HTP2B are implicated. In fact, 'norfenfluramine was found to be two orders of magnitude more potent at 5-HT$_{2B}$ and 5-HT$_{2C}$ receptors compared with 5-HT$_{2A}$ receptors' (Hutcheson, 2011). While we have some information about the affinity of LSD towards different receptors, we have little information about how its unique 'crystal structure' may result in different heart health outcomes (Wacker *et al.*, 2017).

Affinity does not tell the whole story. The doses of Fen-Phen used in the 1980s and 1990s far exceed the doses used in microdosing, seemingly resulting in several orders of magnitude more *activity* at the receptors. Additionally, in the cases of heart valve disease in Fen-Phen, all of the patients were symptomatic. Of the thousands of people who microdosed, no one has reported any heart valve trouble during their period of microdosing, and many people have been microdosing for over a year. All the people we have surveyed with heart problems had them before they started microdosing.

The problem, and it is a very real one, is that this article will be reviewed and popularized over the many different psychedelic and general media sites with varying degrees of accuracy. Since it is highly unlikely that large-scale long-term research necessary to investigate this possibility will ever be funded, the concern will never be validated or disproved. There were a number of frightening scenarios raised about psychedelics during the earlier research era, about LSD in particular, none of which were ultimately verified. However, their wide circulation led to considerable and unnecessary fears among millions of individuals using these substances. We need be careful not to create such fears before we have evidence. Given the serious and multiple warnings given out with most prescription medicine, that there might be unknown side effects to microdoses is to belabour the obvious.

We would look for an expansion of the receptor research (Question 7). It would be a great gift to all psychedelic research if studies could begin to go beyond measuring 5-HTP2A receptors and include, at least, the mTOR and TrkB signalling pathways as well (Ly *et al.*, 2018).

A question to investigate is how the well-described accelerated neural plasticity of a number of psychedelics at high doses is diminished or intensified through periodic microdosing. Early speculation by Kornfeld (Kornfeld and Fadiman, 2013) has now been artfully demonstrated by the work of Ly's group (Ly, *et al*. 2018). This seems to be an especially fruitful area, given the growing body of research linking neural plasticity with both mental illness and recovery.

We are encouraged that in Question 8, the authors went beyond 5-HTP2A receptors and looked at peripheral tissues with doses well below behavioural thresholds as well. We hope the number and kinds of physical systems evaluated for effects continue to expand. For example, although it is now generally accepted that the number of neurons that exist outside of the brain exceeds the number within it, psychedelic researchers have not yet developed research methods to measure changes in gut neurons due to the effects of psychedelics or how those changes affect human biology and behaviour.

Finally, the issues of dose and schedule remain critical. While many pharmaceuticals have a given activity and that more or less of a dose leads to more or less of the same activity, this is not true for psychedelics at higher doses and far less so for microdoses. One size does not fit all, so that the identical dose, however calculated, will not yield the same results across individuals. This may be a hard problem, especially given the few research models popular in pharmacology in general. As for the effects of multiple doses over time, there has never been a suggested protocol that did not include days without dosing, in contrast to almost all psychiatric medications that warn of potential serious health issues if even a single dose is missed. For this and other reasons, psychedelics do not fit neatly into much of current psychopharmacology and thus need to be researched.

Our few concerns aside, these research proposals are a major step forward for psychedelics in general and microdoses in particular.

Psychedelics and creativity

I would recommend not mentioning just these very few anecdotal cases in respect to creativity and psychedelics. There are some good studies and reviews about the subject (Hartmann, 1969) on 40 prominent painters at the German Max Planck Institute of Psychiatry in Munich and the review on the subject by Krippner (1985).

When it comes to the very few studies looking for low doses of psychedelics and creativity (review in Passie, 2019), no study revealed any significant/relevant effects under controlled scientific conditions (e.g. McGlothlin *et al.*, 1967). The study of Prochazkova *et al*. (2018) claimed (under weakly controlled conditions in respect to dosing and environment) increased lateral thinking, which has been discussed as a marker of creativity. This study employed doses of psilocybin that were above the perceptible level (4-8 mg p.o.). However, increased lateral thinking does not mean that the drugged subjects have shown increased creativity in a valid sense, e.g. creating more original painting.

Definitions: Microdosing and minidosing

I do not agree with the authors' narrow definition, since it does not reflect fully what is used in the literature and the appropriate Internet entries. It has been proposed that the term 'mini-dosing' could be used to separate the approach of taking small perceptible doses. It is also clear that many authors and Internet entries suggest the practice of just taking one dose at a time rather than a few ones consecutively as, for example, seen with the Fadiman scheme. This is also valid for taking a tenth or a twentieth of a usual dose. However, the issues related to definitions point towards the question/definition of what is considered a 'full dose'. In the case of LSD, some authors reasonably argue that 150 µg is a full dose (especially in females), whereas others consider 250 µg a full dose. This is a significant issue, because 15 µg is usually not perceptible by most subjects, but a dose of 25 µg is for most subjects (as shown in some scientific studies). Therefore, the definition has to be sharpened before scientific consensus can be reached and the evidence from so-called microdosers disseminated on the Internet as well as studies of anecdotal evidence (e.g. Johnson, 2018), which suffers from such inaccuracies, can be taken seriously.

Dosing of dried mushrooms

Plant/fungal material is generally quite unreliable for calculating a dose. I do not agree with the author's statement that 3.5 g *P. cubensis* is 'a usual recreational dose'. Most recreational users take 1 to 2.5 g as a recreational dose, which is also recommended in most books in the field. From my experience, and the research studies of Abramson and Rolo (1967), I would state that a dose of psilocybin below 3 mg is below the perceptible range. Usually, doses above this level can become apparent. For example, Prochazkova *et al*. (2018) used 4-8 mg psilocybin, i.e. more than a microdose, thus, more consistent with the definition of what might be considered a minidose.

The most used dosing regime and effects of micro- and minidosing

It can be easily seen in Internet entries that most subjects who take microdoses recreationally for 'bettering performance' take doses that give them some perceptible effects. Even a microdosing proponent like Paul Austin recommends doses where you can feel/perceive some alterations to some extent. How would you better your performance if nothing can be felt from a dose?

Following my comprehensive research into this topic (Passie, 2019), I have never come across anything about a 'workaholic approach' (dosing during weekdays, but not on weekends) as suggested by the authors. This also does not make much sense form a pharmacological point of view, because tolerance to LSD develops very quickly. Be reminded, that the US military has dosed soldiers with increasing daily doses to try to make them 'immune' to LSD's effects (Ketchum, 2006).

I think that a minidose (e.g. 20 to 50 µg LSD), in contrast to a microdose (which I define as something below 20 µg LSD, e.g. 5-15 µg), makes a significant difference in terms of recreational as well as scientific studies as it definitely alters psychological functioning and the cognitive system.

However, this alteration is not in any way equivalent to stimulants like Ritalin or amphetamine as is sometimes reported anecdotally. It is more a dissociation from the environment and the person itself. Cognitive abilities have been proven to be compromised in many studies with LSD and psilocybin employing a very low dose range (Passie, 2019). It is also important to register these (potentially) distracting effects. There are also a few scientific reports of people who have been given very low doses of LSD for treating depressive mood. These had negative results with very few patients experiencing a small improvement.

What is plausible (and has been experienced by this author) is that a minimal sympathomimetic effect (for sure not compatible with any sort of usual stimulant!), which might be still there up to 20 hours after a 10- to 15-µg dose of LSD, can cause problems with falling asleep, especially in sensitive persons. It is of interest how long it takes following intake for effects to occur. One could think of a train of effects induced in the organism, which is pushed on and may influence the organism even after virtually all of the substance has left the organism.

I definitely do not see the Fadiman protocol (5-15 µg LSD every third day) as the most used approach. It might be viewed as the most widely known, but by far (!) the most 'microdosers' use one occasional dose, not a regular intake. This also makes it very questionable what effects can be/are felt or not, especially when it comes to taking 10 µg just a few times per year (which is apparently what most users do). As Fadiman's coworker on his more or less systematic Internet surveys, Sophia Korb has mentioned in a lecture (conference 'Beyond Psychedelics', Prague 2018) that they know of just three persons who have dosed regularly (according to the Fadiman protocol) for more than 3 weeks. These three subjects were terminal cancer patients and felt quite normal up to day 50. Between days 50 and 60 they all became much more psychologically labile, i.e. having larger mood changes (in the positive as well negative direction, with daily fluctuations), as measured using the PANAS scale.

To my mind, the study published by Horsley *et al*. (2018) does not have any seriously calculable implications for humans. Its limitations should be discussed.

Possible alterations of gene expression and receptor proteins

There are serious doubts that the repeated doses of LSD, which have been used in rodents, are comparable to microdoses in humans. I am not an expert on interspecies scaling, but, for example, (just by simplified arithmetic) the studies by Martin *et al*. (2014) have used doses which are 12,000 times higher than a microdose in humans. According to a recent review (Sharma *et al*., 2009), it appears not to be congruent with scientific data to state that the dose used by Martin *et al*. (2014) is in any way comparable to a microdose in humans. Therefore, to date we know nothing about possible changes in gene expression induced by regular LSD intake in humans.

I doubt that the gene/BDNF changes which were found with very high daily doses in animals can be scaled up to humans using microdoses every few days. Issues of adaption and tolerance should be discussed in this respect.

Receptors are proteins. These proteins and others might be altered by repeated intake of, e.g. LSD, even in very low doses (Buchborn *et al*., 2016). Even if this is somewhat speculative, it seems probable.

On the possible induction of cardiovascular valvopathy

In respect to a possible induction of cardiovascular valvulopathy by chronic 2-HT2R activation, it is worth mentioning that the studies of Bender and Sankar (1968) in the 1960s involved doses of 100 µg LSD for up to

35 months on a daily basis without any observable damage. However, their methods of investigation might not have been sensitive enough to detect damage. It is also true that just a very small part of the patient population taking ergot compounds (e.g. methysergide) do in fact develop valvulopathy. It is also worth mentioning that if a valvulopathy is detected in a patient, in all cases it disappears within a short time after stopping the medication. There is just one case documented in the literature where surgery was necessary (Graham, 1967).

We would like to thank the four respondents for their thoughtful and insightful contributions to this work. We should also like to make it clear that in addition to their commentaries they also made significant observations on our critique pointing out some errors and omissions that we have taken account of to improve the manuscript. Please read the critiques with this in mind as some of their comments have now been dealt with in our text.

We were pleased that all felt it a significant contribution to the field. They also have significantly enlarged the scope of our review with their very helpful contributions to aspects such as current practice, impact on creativity, value and relevance of rodent studies to mention but a few. Where necessary we mention these issues below though much of their comments and additional insights and references reflect their extensive expertise in this field, and we are very grateful for these as they significantly improve the scientific scope and value of this critique.

A couple of their points need addressing, starting with terminology. We like the distinction made between minidose and microdose and would be happy to see this in use. A minidose being one that has a detectable effect whereas a microdose does not. Of course what the actual drug amount is for each is uncertain, and to what extent the psychoactive effect of a minidose might be 'allowed' to have and still be called 'mini' would need more consideration, but until then, Passie's suggestion of 5-15 µg LSD makes sense, though Liechti's observations need also to be taken into account.

We accept that our focus was on psilocybin and the reason for that was simple - it is almost certainly going to be the first serotonergic psychedelic made available as a medicine. For this reason, it is also currently the only psychedelic made to GMP standards and approved for medical trials with patients. This means that psilocybin is the best choice for microdosing research, certainly in patients and also for volunteer studies in countries where GMP production is required for healthy volunteers. But we fully agree that LSD should also be studied given its widespread use by the microdosing community. For those who chose to use this psychedelic then Fadiman's and Passie's approaches would make a good starting point.

The problem with all psychedelic microdosing studies is how to do it legally and ethically, and this is the big question that needs answering. Maybe a change in the regulations to exclude microdoses from the list of controlled drugs could be sought? After all, when used singly they are below the threshold for subjective effects and so are not psychoactive.

Overall, we are pleased with the results of our efforts and those of the reviewers. Microdosing is a current phenomenon whose value and safety are uncertain. Much research is needed to properly evaluate the personal psychological and health claims. We hope that this set of papers will give impetus to this research and also set it in a solid framework.

Microdosing - Improving performance enhancement in intelligence analysis

by

Maj Emre Albayrak

Marine Corps Gazette - February 2019

Maj Albayrak has been an Intelligence Officer for twelve years and is also an Expeditionary Ground Reconnaissance Officer. He has recently completed a tour as the Operations Officer for the Intelligence Support Battalion in an Inspector-Instructor capacity.

"No problem can be solved from the same level of consciousness that created it."
- Albert Einstein

The Marine Corps Intelligence, Surveillance, and Reconnaissance Enterprise (MCISRE) may gain an advantage over competitors in intelligence analysis, productivity, and efficiency if it utilizes the innovative cognitive benefits gained through microdosing with psychedelics, which scientists, Silicon Valley executives, disruptors, and biohackers have already harnessed.

Step into any sensitive compartmented information facility in the Marine Corps and you are guaranteed to find any number of stimulants and performance-enhancing drugs (PEDs): caffeine and tobacco in many forms, lab-manufactured and non-Food and Drug Administration-approved pre-workout supplements, etc. The presence of these substances makes it clear that the Marines working within these facilities are attempting to extend their wakefulness while increasing their efficiency and productivity. The increasing speed and breadth to which we collect raw data for processing and exploitation in the fourth generation of warfare,[1] where data flows in terabytes (a thousand gigabytes) and petabytes (a million gigabytes), creates enormous analytical and cognitive challenges.[2, 3]

These challenges create a discrepancy between technological capability (what we can collect) and human ability (what we can process, exploit, and distribute). Intelligence professionals in MEF intelligence centers work on problem sets that require lateral thinking, logical reasoning, persistence, close attention to detail, and creativity on a 24/7/365 processing, exploitation, and dissemination cycle. These Marines are asked to be superhuman and compete in intelligence where, like professional athletes, one percent gains provide significant advantages. Therefore, these Marines are attempting to leverage unique biological reactions to increase cognitive ability, efficiency, and "flow," much like hyper-competitive, information-hungry, self-motivated scientists, Silicon Valley executives, and CEOs.

Enter Psychedelics

Prior to the well-known and documented recreational usage of lysergic acid diethylamide (LSD) and psilocybin (the alkaloid found in hallucinogenic mushrooms) in the 1960s, scientists, researchers, psychiatrists, psychologists, and the U.S. Government tested psychedelics in over 1,000 different studies. Introduced as medication for psychiatric use and growing in medical popularity, *Time* magazine published multiple positive reports on LSD during this time.[4] Beginning in 1953, the Central Intelligence Agency began a program of experiments under the project name MKUltra. The intent of this program was mind control, tested through experimentations on human subjects to identify and develop drugs and procedures that could weaken defense mechanisms during interrogations.[5] A large portion of subjects were administered LSD without informed consent, warning, or appropriate control mechanisms.[6] Unable to achieve the desired results, MKUltra was halted in 1973. During the height of the MKUltra experiments, however, psychedelics continued to gain popularity as research drugs. From 1947 to 1966, researchers wrote over 1,000 scientific papers, published several dozen books, and dedicated six international conferences to the study of psychedelics. The parallel recreational popularity of psychedelics and the resultant moral panic led to Federal laws banning LSD in 1966. This ban also halted legitimate scientific studies, suppressing any further scientific research.

Currently, psychedelics are experiencing a third-wave resurgence - the first wave was the traditional use by native peoples from civilizations around the world for thousands of years, the second wave was the heavy scientific and recreational usage in the 1960s that resulted in their ban, and the third wave is the current use of LSD and psilocybin to assist in medical and psychological situations, including recent Food and Drug Administration-approved studies by researchers at Johns Hopkins, Yale, NYU, and various other facilities who have confirmed the positive cognitive effects of psychedelics.[7, 8] Scientists, Silicon Valley executives, biologists, biohackers, and others who face complex problems or operate at high performance levels are also using microdosing to gain a mental advantage with psychedelics.[9]

Microdosing

A microdose is a sub-perceptual amount (i.e., it does not cause perceptual sensory changes such as visual hallucinations and is *not* strong enough to debilitate the subject) consisting of about a tenth of a medicinal dose of any given psychedelic, usually between 10 and 20 micrograms (μg) of LSD or 100 milligrams (mg) of psilocybin. In research, microdoses were reported to significantly heighten alertness, creativity, and problem-solving - inducing a "flow state" that aids in lateral thinking. Like most hallucinogens, LSD mimics the effects of serotonin (a mood regulator) and activates 5-HT$_{2A}$ receptors in the prefrontal cortex. This increases the activity of the chemical glutamate, which enables the transmission of signals between nerve cells and plays a role in learning and memory.[10] Researchers at the Centre for Neuropsychopharmacology at Imperial College London carried out groundbreaking imaging studies showing changes in cortical functions of the brain (see Figure 1).

Microdoses cause cortical functions to be more fluid, leading researchers to believe that psychedelics may help certain brain areas work in increasingly flexible and expansive ways.[11] The study further states that LSD decreased blood flow to the "default mode network" (DMN), an area of the brain that is activated when the mind is wandering, not committed to a task, and thinking about one's emotional state - what is generally viewed as the "ego."[12] A person's problem-solving ability is typically constrained by his ability to think beyond his limited set of experiences housed within the DMN, and attempts to find solutions are typically made from past experiences. As psychedelics decrease DMN activation, individuals have been shown to expand their ability to connect seemingly unconnected pieces of information and create revolutionary new solutions. The enhanced availability of cognitive pathways, in addition to the changes in cortical functions brought on by microdosing, enhances lateral thinking and creativity,[13] both of which are critical for problem-solving and analytical thinking. These findings support the abundant anecdotal evidence such as Nobel Prize-winning scientists admitting their use of small doses of LSD to boost thought.[14] Psychedelics are credited as a cause for the emergence of personal computing from a select group of government- and corporate-funded laboratories, and even Steve Jobs claimed, "Taking LSD was a profound experience, one of the most important things in my life. LSD shows you that there's another side to the coin."[15]

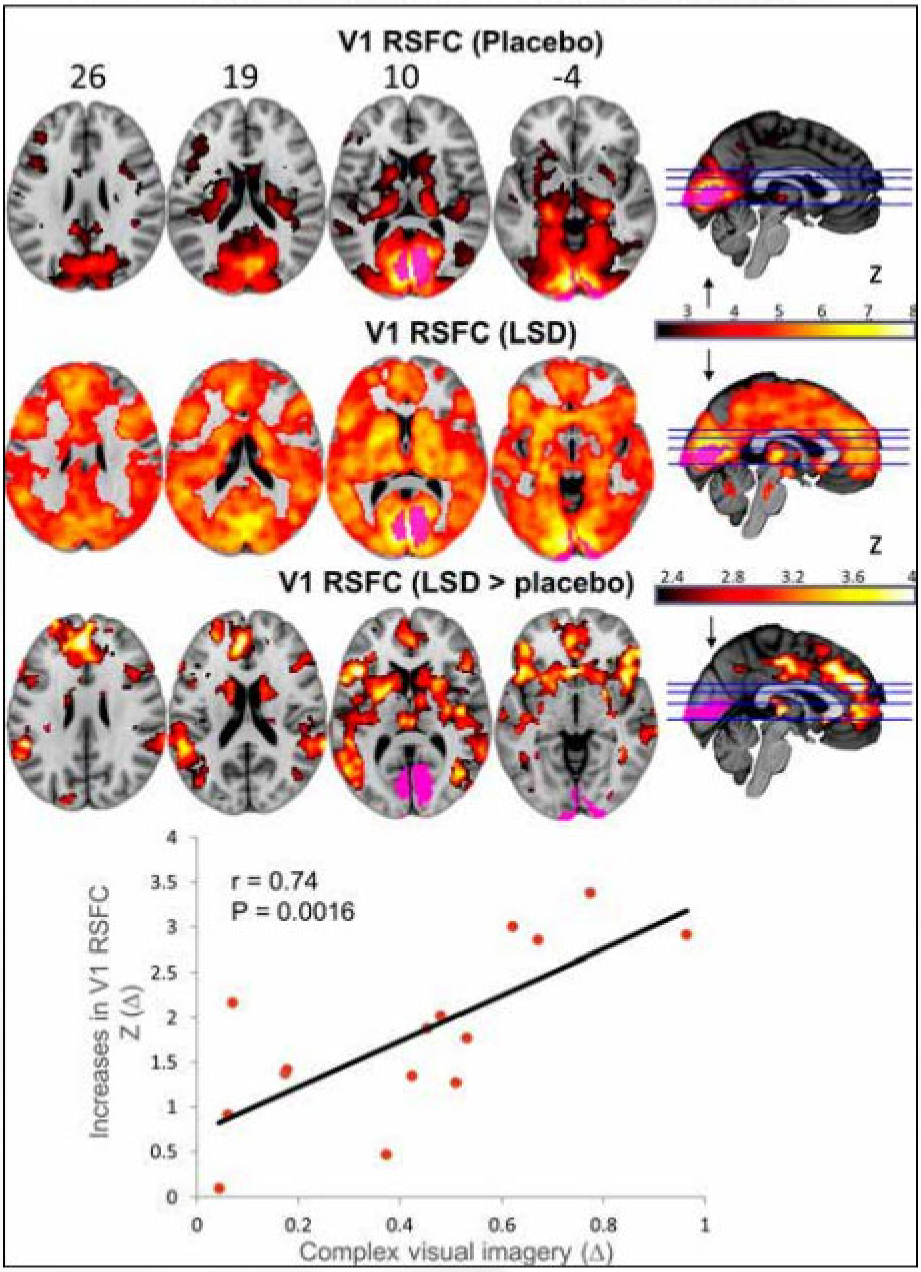

Figure 1. Significant between-condition differences (orange = increases) in Resting State Functional Connectivity (RSFC) between the V1 seed region (purple) and the rest of the brain. Un-thresholded maps can be viewed here: neurovault.org/collections/FBVSAVDQ/

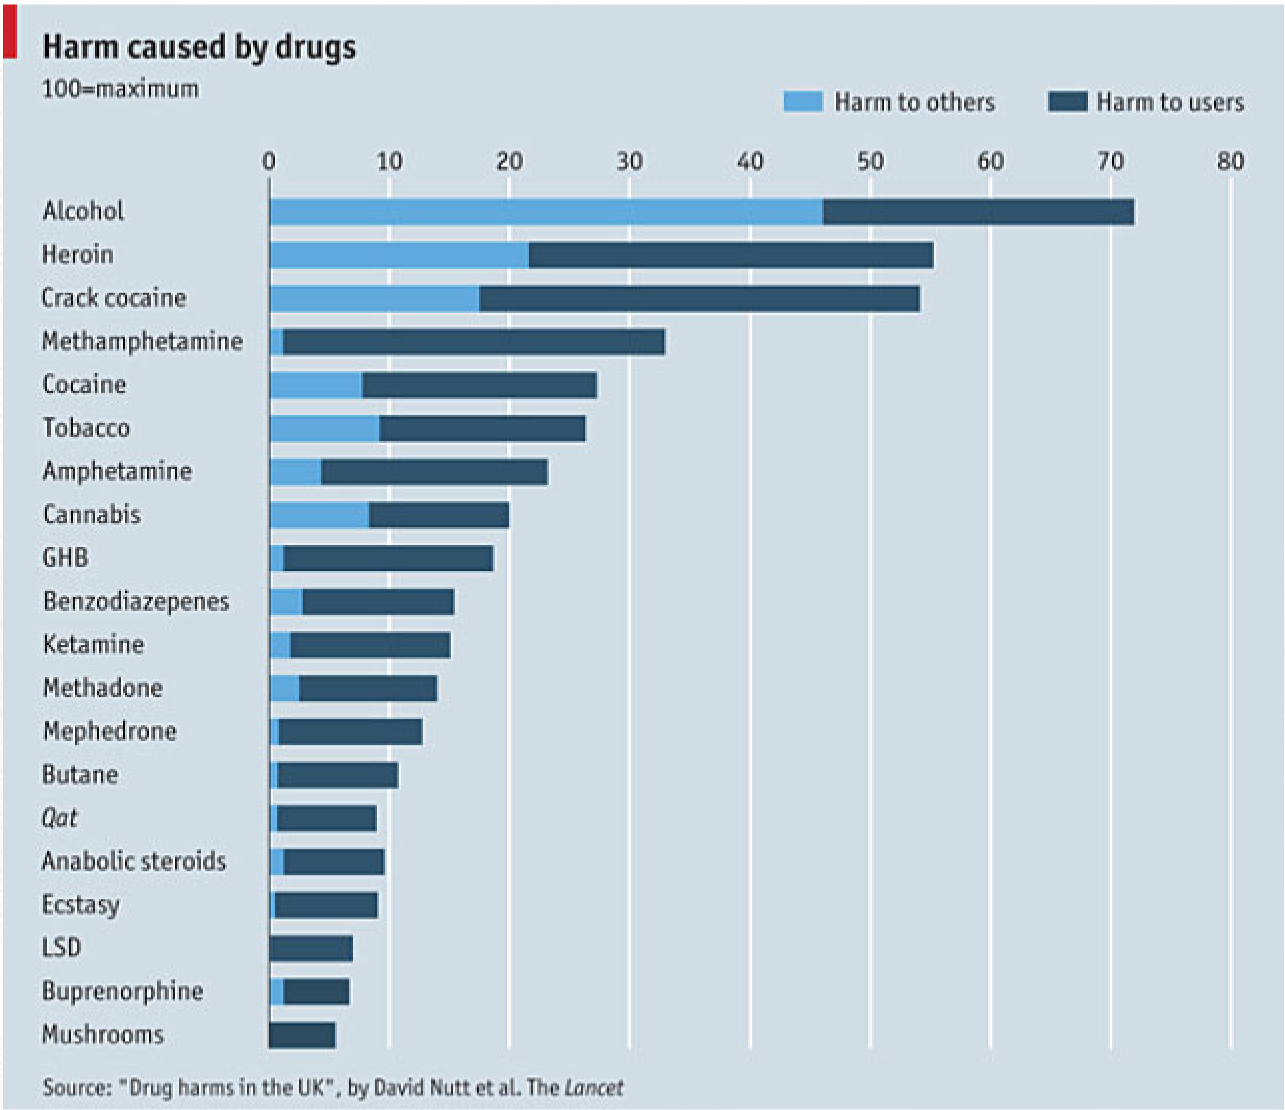
Status Quo

Currently, Marines across the MCISRE regularly use a variety of PEDs to accomplish their tasks. The most well-known PEDs, caffeine, pre-workout supplements, and tobacco, all have some positive short-term effects. However, they do not significantly elevate cognitive activity, enhance neural pathways, or disrupt the brain's DMN. Additionally, existing stimulants have proven negative effects, including jitteriness, energy crashes, elevated heart rate, and, in extreme cases, cancer. Some use PEDs such as Adderall, Ritalin, and Modafinil, albeit with less regularity. These PEDs are effective tools when utilized for their intended purposes; however, the offlabel use for drugs such as Adderall[16] and Ritalin[17] have shown ambiguous improvements in cognition or no improvement at all - undesirable when attempting to solve "wicked problems."[18] Additionally, both of these drugs are amphetamines and carry a variety of side effects: rhabdomyolysis, kidney failure,[19] and a high risk of addiction. Modafinil has shown potential as a cognitive enhancer in certain tasks,[20] but the chief use of Modafinil in the MCISRE is currently limited to reconnaissance Marines or snipers beyond the forward line of troops on extended reconnaissance and surveillance missions where fending off exhaustion is necessary for survival. Despite studies showing Modafinil as a cognitive enhancer in complex assessments,[21] military medical officers do not regularly prescribe service members with Modafinil for off-label uses.

In contrast, microdosed psychedelics enhance cognitive function and flexibility, lateral thinking and creativity, elevate mood, and decrease DMN activity. These factors allow the brain to operate in a manner free of preconceived notions or boxes, resulting in greater creative problem-solving abilities.[22] Psychedelics, however, are not without side effects. The most prevalently cited concerns include purity, dosage control, uncontrolled environments, and their illegality. Unlike amphetamines, psychedelic use does not lead to physical dependence.[23] Overdosing from the direct pharmacological action of LSD in humans is not a salient fatality concern.[24] LSD and mushrooms demonstrate the least amount of harm to users and others amongst drugs[25] (see Figure 2), and LSD does not remain in the spinal fluid or spinal cord, as it was once believed.[26]



Harm caused by drugs

100=maximum

Source: "Drug harms in the UK", by David Nutt et al. The *Lancet*

Figure 2.

Gaining the Advantage

War is not a game, and meeting your enemy on equal footing is a fool's errand. The United States plans to spend $717 billion on defense in fiscal year 2019 to ensure that America has the most lethal, flexible, and responsive military in the world.[27] America dedicates resources to making its military stronger, faster, and smarter than our adversaries, and we are searching for advantages everywhere. Combat does not reward fair play, and World Anti-Doping Agency doping control officers are not taking samples after missions to ban Marines from "competition." Our enemies are already seeking an edge over us through PEDs and nootropics,[28, 29] and our own units, such as the Naval Special Warfare Development Group, seek cognitive advantages via unorthodox methods such as mind gyms and sensory deprivation tanks.[30] The cognitive advantage they seek is "flow" - or "ekstasis" from the Greek, which Plato describes as "an altered state where our normal waking consciousness vanishes completely, replaced by an intense euphoria and a powerful connection to a greater intelligence."[31] This phenomena is described as a non-ordinary state of consciousness in which individuals tend to have heightened focus, pattern recognition, and reaction time. Flow can be observed in a seasoned close-quarters battle team clearing a complex structure. Scientists solving complex problems have described flow; a 10-year McKinsey study revealed top executives being 500 times more productive while in flow.[32] Flow state is understood, but those able to achieve flow on demand cannot easily guide others into it. Research suggests it takes significant experience (in some cases 10,000+ hours of meditation)[33] to quiet the DMN and enter flow on demand.[34]

One thing is clear, a flow state provides a distinct advantage, and the ability to achieve "flow on demand" could provide a significant cognitive advantage. Flow states have been entered with microdosing, and research supports the idea that a cognitive advantage can be gained. Through well-designed experimentation and the use of psychedelics in intelligence analysis, an advantage may be gained over our adversaries.

Testing and Integration into Intelligence Analysis

"The MCISR-E is a warfighting enterprise that supports decision-making through the provision of tailored intelligence that is timely, relevant, and predictive."[35] It does so through its incorporation of a 24/7/365 predictive analysis process led by the MEF intelligence centers and tied into the Marine Corps Intelligence Agency and the intelligence community. The MCISRE is additionally tasked with harnessing human capital and innovation to meet future challenges,[36] the former being exactly where microdosing and intelligence analysis will intersect.

The challenge of unsolved or particularly difficult problem sets is attempting to solve the problems on the current level of cognition either prolongs the time to solution or leaves the problem unsolved. These outcomes are suboptimal in a 24/7/365 environment that requires rapid intelligence analysis for crisis response. Microdosing could be tested in a controlled manner with a select group of volunteers under a special access program to see if significant gains could be made in intelligence analysis productivity and efficiency - especially on particularly difficult problem sets. With specific guidelines, this hypothesis could be evaluated utilizing a double blind method, either independently or as a joint venture with the Defense Advanced Research Projects Agency. First and foremost, all test subjects must be volunteers and provide explicit consent. All volunteers should have a high general technical score (110+) and be mature and experienced analysts (8+ years of experience), heavily invested in difficult problem sets, well versed in their area of expertise (subject-matter experts), and screened for behavioral/psychiatric issues (PTSD, anxiety, panic attacks, previous and current prescription and recreational drug use). It is obvious this will be in direct contravention of the Marine Corps substance abuse policy, which is why these Marines will have to be very carefully screened and selected. The volunteers will need drug waivers entered into their medical files and must be subject to additional weekly drug screenings to ensure they are only ingesting substances prescribed in the study. The group will be separated into test and control groups, with the test group being administered microdoses in accordance with current microdosing guidelines of 10μg of LSD or 100mg of psilocybin every three days[37] and the control group being administered no substances. Following microdosing, the groups will be tasked with competing in the popular Asian strategy game *Go*, which can be utilized to assess cognitive expertise and functions such as attention, working memory, visuospatial processing, and decision making.

Go should be utilized as a benchmark test because presenting test subjects with previously answered problem sets (*a' la* tactical decision games) will not be scientifically sound (a subject may know the solution or have privileged access to information that could lead to solving the problem). Current unsolved problem sets will also cause an issue because the problem may continue to go unsolved without setting a benchmark for how much cognitive improvement is made between the test and control groups. Additionally, Google has utilized *Go* to test the strength of its artificial intelligence program,[38] and it stands to reason that this evaluation will be relevant in this field as well.

The MCISRE provides a young, healthy, and educated population that is under comprehensive medical coverage and supervision. The virtue of close medical supervision, the ability to obtain pure microdoses, daily oversight, and the controlled application of dosage makes the MCISRE a perfect incubator for this experiment. If gains in this study were statistically significant, they could move to small, dedicated, microdosing analyst groups working on wicked problems.

Closing

Though the idea is radical, it must be understood that this is neither a sideways attempt to allow Marines to ingest illicit substances nor to be mistaken as a half-baked attempt to recreate previously failed paranormal experiments such as the Army's *The Men Who Stare at Goats*.[39] This is a serious foray and discussion about considering the use of cognitive PEDs to increase productivity, creativity, problem-solving ability, and flow. If such an experiment were initiated and found to provide a cognitive edge, the DOD and MCISRE, in concert with the data aggregation tool and other technological advantages available, would leverage an untapped resource to create an insurmountable gap over every other competitor.

Powerful substances in tiny amounts

An interview study of psychedelic microdosing

Abstract

Aims: This article presents a qualitative interview study of people who microdose with psychedelic drugs, which means that the user takes about one tenth of an ordinary recreational dose. **Design**: Respondents (n = 21) were recruited at several Internet fora for individual interviews via private messaging. Every participant was male, and the median respondent was in his 30s with a stable job and relationship and extensive entheogen experience. **Results**: Respondents tended to experiment with microdosing in phases, reporting mostly positive consequences from this form of drug use. Reported effects included improved mood, cognition, and creativity, which often served to counteract symptoms especially from conditions of anxiety and depression. There were also reports of various challenges with psychedelic microdosing, and some did not find the practice worth continuing. **Conclusion**: The study obtained evidence of a group of users taking small doses of psychedelics not for the purpose of intoxication but to enhance everyday functioning. While the study's findings are not generalisable, they may inform subsequent investigations with research questions and hypotheses.

Keywords enhancement, health effects, interview, microdose, psychedelic, qualitative

Introduction

To microdose with a psychedelic drug means to take a dose small enough to provide no intoxication or significant alteration of consciousness. Microdosing has been growing in popularity and visibility since James Fadiman recounted some self-experiment reports in his 2011 book *The psychedelic explorer's guide*, but has roots going back to 1970s psycholytic therapy and, according to Fadiman (2011), to indigenous healers and shamans who have "systematically and fully explored every dose level" (pp. 198-199). The microdosing phenomenon has spread most recently over the Internet, where discussion fora enable users to share experiences and exchange information in ways that make new practices accessible for others. Its growing visibility has been reflected in substantial recent media coverage, with a number of reports especially about students and professionals microdosing with LSD in order to improve their concentration and problem solving (Nørgaard, 2017; Solon, 2016; Tande & Fliflet, 2017; Tollersrud, 2017; Williams, 2017). The overall impression from these reports is that microdosing affects mood, health, and cognition in generally positive ways, while allowing the user to carry on with everyday activities.

Searches through PubMed, ProQuest and Google Scholar databases confirmed that there was at the time of writing no published research on psychedelic microdosing to corroborate these anecdotal findings. However, much attention was given to the effects of larger doses of psychedelic substances by psychiatric researchers in the 1950s and 1960s, and one noteworthy finding was that psychedelic therapy sessions often resulted in long-term recovery from alcoholism (Abramson, 1967; for a recent meta-study see Krebs & Johansen, 2012). Clinical effect was also observed for a range of conditions including anxiety in terminal cancer patients and obsessive-compulsive disorder (see review in Nichols, 2004). These lines of research were curtailed by political developments, but have reemerged in recent years after a decades-long hiatus (Sessa, 2005). Recent preliminary results have indicated therapeutic effects from full doses of psychedelic drugs on depression and anxiety around life-threatening disease (Gasser *et al*., 2013; Griffiths *et al*., 2016; Grob *et al*., 2011; Ross *et al*., 2016), on substance dependence (Bogenschutz *et al*., 2015; Johnson, Garcia-Romeu, Cosimano, & Griffiths, 2014; Schenberg, de Castro Comis, Chaves, & da Silveira, 2014; Thomas, Lucas, Capler, Tupper, & Martin, 2013), and on various other somatic and psychological conditions (Carhart-Harris & Nutt, 2010; Johnstad, 2015). However, full doses of psychedelic drugs lead to experiences that are often very intense, and which have been reported to induce both acute panic reactions and toxic psychoses (Iversen, Iversen, Bloom, & Roth, 2009). While the notion of a direct relation between psychedelics use and mental health complications is subject to dispute (Hendricks, Thorne, Clark, Coombs, & Johnson, 2015; Krebs & Johansen, 2013), it would seem prudent to conclude that full doses of psychedelics have a potential to incur nontrivial adverse effects.

Microdosing, on the other hand, is not experientially intense, and has not been reported to result in negative health reactions in anyone. We must acknowledge that this use of psychedelics has not yet been described in academic literature beyond basic reports of its existence (Savulich *et al*., 2017; Sweat, Bates, & Hendricks, 2016), and that the current lack of information about adverse reactions is subject to change. Nevertheless, the anecdotal evidence currently available indicates that microdosing seems to be a promising candidate for some of the health benefits claimed for psychedelics while incurring minimal risk for mental health complications. The aim of this study was therefore to explore psychedelic microdose use by interviewing users about their experiences. Common patterns or themes in their responses could serve as hypotheses or research questions for subsequent investigations.

One way to understand the microdosing phenomenon is to see it in light of the literature on human enhancement techniques. Researchers have identified the growing use of enhancement drugs such as piracetam (Corazza *et al*., 2014), methylphenidate and modafinil (Hupli, Didz·iokaite, & Ydema, 2016), especially among university students, and performance-enhancing drugs have long been regarded as a problem in sports. Hogle (2005) analysed such enhancement drugs as an aspect of a broader range of enhancement technologies including cosmetic procedures, cyborg prosthetics, and genetic enhancement, and observed that humans have a long history of voluntary bodily modification. She argued that enhancement technologies differ from therapeutic interventions in that they may not have a starting point in deficiency, but found it difficult to distinguish precisely between the two. In a definition by Coveney, Gabe, and Williams (2011),

> A therapeutic intervention will restore normal or typical functioning with the aim of returning an

> unhealthy person back to a healthy state whereas an enhancement will improve or extend the abilities or capacities of a healthy individual (who is already functioning normally) outside of this normal or typical range. (p. 384)

They found the therapy-enhancement dichotomy to be a useful heuristic, but warned that it may also be limiting because of the ambiguity inherent in concepts such as health and normality.

Normative characterisations of enhancement drug use varied substantially between these researchers. Whereas Corazza *et al*. (2014) spoke of "abuse", Hupli *et al*. (2016) found that enhancement drug use by healthy individuals could best be understood as "functional drug use". Coveney *et al*. (2011) observed that the social acceptance of enhancement drugs rests in large part on the cultural authority of medical experts and may be subject to change. In an assessment of the need to regulate cognitive enhancement drugs, Ragan, Bard, and Singh (2013) found that regulation "would have to aim at minimizing the risks and harms of cognitive enhancement while maximizing the benefits" (p. 593).

Some researchers have also noted that media reports about enhancement drugs tend to exaggerate how widespread their use is and to over-emphasise their benefits (Partridge, Bell, Lucke, Yeates, & Hall, 2011). While I am not aware of any analysis specifically of media reports on psychedelic microdosing, it is possible that media coverage of this phenomenon conforms to the same pattern.

Method

Terminology

In this article, the term "microdosing" is used exclusively in the context of psychedelic drugs. However, the definition of the term "psychedelic" was unspecified in communication with respondents, and some mentioned microdosing experiments with drugs such as cannabis, which are not usually classified as psychedelics. These reports are noted briefly in the results section. Experiences of perceived therapeutic or enhancement effect are referred to as "positive", whereas unwanted effects are labelled "negative".

Study design

Using purposive sampling, current or former microdose users of psychedelic drugs were recruited for interviews via a variety of Internet fora dedicated to discussions of various psychedelic experiences. Only one of these fora was dedicated especially to microdosing, but there were usually at least a few discussion threads about the subject on each forum. Recruitment efforts used two separate strategies: one was to post a new thread describing the purpose of the study and asking for input, and then to contact individual users by private message for further questions; the other was to search the forum for previous entries relating to microdosing practices and then to contact eligible participants by private message. This two-pronged recruitment strategy was employed on seven different user fora, of which *The Shroomery*, *DMT-Nexus*, *NorShroom*, and *Reddit* produced a range of responses, while *The Hip Forums*, *Psychonaut*, and *Bluelight* did not produce substantial numbers of responses. Forum members who responded to initial recruitment efforts or had made noteworthy contributions to old discussions ($N = 24$) were contacted via private message. Some users who had tried microdosing only once or a few times without any noteworthy effect were not contacted for further interviews as I had nothing further to ask of them, but their experience of no effect is nevertheless noted in the results section. Three of the 24 eligible participants did not respond to the private message, while the remaining 21 gave their informed consent to participate. The study was designed in conformity with Norwegian Social Science Data Services ethical guidelines. A few quotations have been translated from Norwegian, and statements have been edited for brevity and relevance.

Because psychedelics are generally illegal, not all respondents were willing to provide demographic information. In order to reduce participation stress, only a minimum of such information was requested. Every respondent was male. Of the 17 who listed their age, the median age was early 30s. Four were single, five in a relationship, and eight engaged or married (three with children). Five participants were students, while nine were in full-time employment variously as a factory worker, a biologist, a hospital worker, a teacher, a cook, a plant scientist, and in IT security; one was self-employed and two were unemployed/disabled. Five, including one of the unemployed, held master's degrees or PhDs. They had from one year to 25 years of experience with psychedelic drug use, with the median length of experience amounting to about 10 years. Thirteen had extensive microdosing experience and eight had experimented on a more sporadic basis.

In their discussion of Internet recruitment for qualitative studies, Hamilton and Bowers (2006) found that one of the strengths of this recruitment strategy was the potential to increase the appropriateness of each participant. This was indeed the case in this study, as each of the 21 interviewees made valuable contributions and must be regarded as highly appropriate for the study. It is difficult to imagine any non-Internet recruitment arena that could have provided the same level of access specifically to psychedelic microdose users. However, Hamilton and Bowers (2006) also found that participants recruited on the Internet probably have more education and higher incomes, thus potentially skewing findings. While the Internet is probably more accessible today to those with lower education and income levels than it was in 2006, it may very well be the case that Internet recruitment in this study served to exclude some drug users. Furthermore, users with some enthusiasm for psychedelic drugs were probably more likely to self-select for the study. The recruitment process therefore did not obtain a representative set of participants reflecting the general population of psychedelic microdose users.

Interviews were asynchronous and Internet-mediated, and conducted on a semi-structured basis. Such forms of interviewing have been validated by Meho (2006), who discovered a broad range of medium effects from using email to convey interviews. Advantageous effects included a possible increase in honesty and self-disclosure, as well as the elimination of transcription errors, while disadvantages included the loss of visual and nonverbal cues from facial expressions and body language. In conclusion, Meho found no overall negative impact on data quality. Consistent with Meho's finding of an increase in self-disclosure, Bargh, McKenna, and Fitzsimons (2002) discovered that the relative anonymity available on the Internet afforded users increased opportunities for expressing aspects of themselves that they would be inclined to hide from others in face-to-face communication. By allowing for a high degree of participant anonymity, email interviews for this study probably served to facilitate participation from interviewees who would otherwise have balked at describing illegal activities to an unfamiliar researcher. According to Hamilton and Bowers (2006), another benefit of asynchronous email interviewing is that it affords the researcher the opportunity to reflect on previous responses from the interviewee and, on this basis, to pose more thoughtful follow-up questions than might be possible in a face-to-face conversation. I found this feature to be beneficial for the interviewing process.

Typical questions used to guide the interview were:

1. Which psychedelics have you microdosed?
2. How much experience do you have with microdosing?
3. Do you microdose in cycles or continuously? How often do you do it?
4. What effects do you get from microdosing?
5. Have you noticed any negative effects?
6. How do you feel the day after a microdose?

Recruitment for the study was continued until new responses consistently conformed to patterns identified from earlier responses, at which point significant new information was deemed unlikely to emerge. Most interviews were completed within a few weeks, but some were extended for several months in order to obtain information about ongoing microdosing practices. As interviews took the form of written communication, transcription was unnecessary. Data were analysed using thematic analysis and Kvale and Brinkmann's (2015) procedure for meaning condensation. Statements from interviewees were shortened and categorised according to topic, and themes were thereupon constructed on this basis in an open-ended, exploratory, and data-driven comparative analysis. Topics were a priori areas of interest such as usage patterns, therapeutic effects, and negative side effects, while themes represented areas of agreement related to a given topic among a group of interviewees. Participant statements were accepted at face value, and there was no theoretical interpretative framework informing the analysis. However, the interview process allowed for critical perspectives and for the resolution of ambiguities through follow-up questions. Participants were asked to read through and verify the use of their quotations.

The study emphasised the preservation of participant anonymity, and aimed to ensure that no participant would be identifiable either to the researcher or to readers of publicised material. Participants communicated via anonymous messaging that protected their identity at least from the researcher. Unless they were using camouflage technology such as The Onion Router (Tor), their IP addresses would have been accessible to the forum service provider, but this would not have served as a privacy concern beyond the risk they were already incurring through their normal use of this forum. Participants were encouraged not to reveal information about their location, background or circumstances that might indirectly reveal their identities. Their pseudonyms are not reported, as these are often traceable across a variety of Internet sites, and demographic information has been delinked from narratives. While full Internet anonymity is elusive, I believe that participation in the study did not compromise privacy to any significant extent.

The emphasis on anonymity entailed that signed consent letters could not be obtained, and incurred the risk that minors might pass themselves off as adults and gain access to a study discussing the use of illegal drugs. However, it is my impression that microdoses are of little interest to minors, and I believe that no attempts at such subterfuge were made. Recruitment letters and later communication with respondents were carefully phrased so as to not give the impression that the author condoned illegal drug use.

Results

Microdose regimen

Respondents generally regarded microdosing as being compatible with most everyday activities. Some would microdose in the mornings of workdays, while others preferred to limit this activity to afternoons and non-working days. The most commonly used psychedelics for microdosing were psilocybin-containing "magic mushrooms" and lysergic acid diethylamide (LSD). There were also reports of microdosing experiences with *Salvia divinorum*, *Amanita muscaria*, *Peganum harmala* (Syrian rue), *Echinopsis pachanoi* (San Pedro cactus), *N,N*-dimethyltryptamine (DMT), 2,5-Dimethoxy-4-methylamphetamine (DOM), and cannabis. Some users had experimented with a broad range of psychedelic substances, while others had limited this use to one specific psychedelic:

> The only traditional psychedelic I have microdosed is mushrooms. I find this to be extremely beneficial spiritually, physically, and mentally but have no experience with other traditional psychedelics as a basis for comparison.
>
> (ID14) I've had good success with Amanita as a daily tonic for wintertime blues. (ID13)

Doses were usually constrained to about a tenth of a full dose. For LSD, this amounted to somewhere between 10 and 25 mcg, and for *Psilocybe cubensis* mushrooms to 0.1-0.3 g. Some reported taking up to a quarter of a full dose, but this was usually regarded as a mini-dose rather than a microdose, and was not found to be compatible with work and everyday activities. Respondents sometimes found it difficult to specify the exact dose they were taking. Some indicated that their microdose regimen was informed by extant literature on psychedelic microdosing. These were some typical statements about dosage:

> I normally cut up a single blotter of 100 or 150 mcg into 8 pieces, giving microdoses in the range of 12.5 to 18.75 mcg. (ID38)
>
> I have microdosed frequently, generally following Fadiman's recommendation of 1/10th of a dose every four days. (ID33)
>
> I dose 10 mcg LSD twice per week. I came to this amount by administering doses at 5 mcg intervals within the following range [5-25]. I have found that 10 mcg is the most beneficial. Any more and I'm a little too impressionable to distraction, any less and there's no benefit. (ID39)

For experienced microdosers, the practice was usually regarded as a cyclic activity, with microdosing periods lasting from a few weeks to a few months. Within such a period, the respondents typically dosed one to three times per week, although some reported dosing on a daily basis. Less experienced users reported occasional experiments without any stable regimen. Dosing a few times a week did not seem to result in significant build up of tolerance (abatement of positive effects), although with one reported exception for DOM. There were conflicting reports on tolerance build up from daily microdosing and about the impact of microdose tolerance on full doses. Some frequent microdose users experienced a build up of tolerance, while others found no such effect:

> In the last year, I have been experimenting with LSD microdoses quite frequently. But in the past two months, I have gone from taking it every third day to every day. What amazes me is the fact that I don't seem to feel any tolerance build up at all. (ID38)
>
> Surprisingly, a one-day break is sufficient for avoiding tolerance. This went against the conventional wisdom online suggesting that a few days in between was necessary. Dosing on consecutive days saw tolerance, then headaches. (ID39)

Experienced therapeutic effects

Respondents generally agreed that proper microdoses (about a tenth of a full dose) of LSD and psilocybin did not result in any intoxication. Some respondents experienced no effect at all from microdosing, and therefore abandoned the practice after a few attempts, but the majority reported some effect that they regarded as positive. The most commonly described effects were health related, with a benign influence noted especially on states of depression and anxiety:

> I have had very positive results from infrequent psilocybin microdosing. I have found fast and relatively long-lasting relief from depression and social anxiety doing this, as compared to other pharmaceutical options I've been offered such as SSRIs [selective serotonin reuptake inhibitors], and without the intolerable (for me) side effects. (ID29)
>
> The best relief I ever had was in the 0.1 g to 0.2 g range of *Psilocybe azurescens*. This helped immensely with my manic bipolar depression and suicidal ideations. (ID17)

Therapeutic effect was also reported for pain management and for a range of conditions including obsessive-compulsive disorder (OCD), post-traumatic stress disorder (PTSD), narcolepsy, and migraines. A *Peganum harmala* microdose regimen was celebrated by some for its help in quitting cigarette smoking. Several respondents reported that they had discovered some psychedelics to work better for their condition than others, but there was no agreement on which psychedelic was most effective.

> I have been dealing with symptoms of narcolepsy for some years now. I would nod off at meetings, telephone calls, and mundane task at the PC. LSD microdoses have really been a game changer. The amount of energy I feel is profound. In terms of quality of life, it is the difference between being a walking zombie, barely keeping eyes open and looking at every daily mundane task as a struggle, and being a normal functioning person with an extra energy boost and creative tendencies. (ID38)
>
> My wife and I had great success in pain management using mushrooms rich in baeocystin and norbaeocystin (*Psilocybe cyanescens* and *Psilocybe azurescens*). Cubensis don't do the same. (ID17)
>
> I have microdosed with psilocybin mushrooms and DMT, both to prevent oncoming migraines from playing out. I cannot say if the tiny amount of mushrooms helped quash the migraine, but the small amounts of vaporised freebase DMT definitely stopped some migraines from playing out to their full extent. (ID34)

Experienced enhancement effects

Besides the effects on health issues, respondents commonly reported what they regarded as a positive influence from microdosing on energy, mood, and cognition. This allowed them to function better in everyday life even when they had no specific health issues. However, the distinction between treatment and enhancement was not always clear. A few respondents microdosed specifically in order to enhance their capacity for academic study or to increase their efficiency in the workplace. These were some typical descriptions of enhancement effect:

> Since microdosing mushrooms, I definitely feel as though a "mental fog" has been lifted and this allows me to be much more productive and functional. (ID14)
>
> I had a great day! Very calm mind, emotionally in balance. (ID23)
>
> I think micro doses can transpire a subtle alpha aura as one navigates the day with fluidity. And you're smoothly infusing your environment with that pure trippy energy that this plasticised world silently begs for. (ID13)
>
> Before microdosing I would have never said I have mental health issues, but I am forced to reconsider as when microdosing I feel I'm living in the brain of an incredibly mentally healthy person. (ID39)

The enhancement of everyday functioning sometimes resulted in an improved capacity to relate to other people. Some respondents claimed that microdosing psychedelics increased their openness and extraversion:

> I feel more open to other people. At home with my family, I feel better equipped to deal with disagreement, and my emotional reactions are less automatic. My mood improves, and I have better contact with my feelings and less restlessness. I more often take the initiative to talk. (ID27)

A few respondents utilised the perceived energy and mood enhancement for spiritual practice, and found microdosing to be helpful in these pursuits:

> I get bright moods, good introspection in meditation, and a generally meditative, contemplative mood. (ID21)

There were also a few reports about combining psychedelic microdoses with full doses of alcohol, cannabis or 3,4-Methylenedioxymethamphetamine (MDMA). These drug combinations were mostly taken for recreational purposes.

> My experience is that a microdose of LSD taken a few hours before a dose of MDMA opens me up, in a sense, so that I feel the MDMA more strongly and intimately. (ID36)
>
> My kids were away, so I spent the day with my wife lounging in the back yard, swimming in the pool. We had some drinks, got high, and I threw back a microdose of mushrooms. We got cozy in the pool, then I took her inside and we made love. Then we made burgers on the grill, smoked more weed and drank more. What a great day. A microdose on a lazy summer day - awesome! (ID10)

Cannabis is known to intensify the effects of psychedelics, however, and one respondent reported a "bad trip" experience resulting from this combination. There were also conflicting reports about the aftereffects of microdosing, with some users finding themselves back to normal the day after dosing and others experiencing a slight change in their energy level. One respondent reported of a sustained relief from anxiety lasting up to a week after a cycle of microdosing. These were some typical responses about aftereffects:

> Today everything is back to normal, I don't notice any improvement or worsening. I have a weak headache, but that may be because I slept longer than usual. (ID26)
>
> I definitely felt an afterglow just like if you dose high enough for an actual psychedelic experience. (ID3)

There was also broad agreement among the respondents that the two most commonly microdosed psychedelics - psilocybin and LSD - were quite different in their effects, and some had developed a clear preference for one or the other. Respondents agreed that LSD had a more stimulating effect than psilocybin, which some welcomed and others found uncomfortable:

> It's weird: I like mushrooms more than LSD, but favour LSD microdoses over mushroom microdoses. LSD is just more practical for work and play, bounding energy and on target mentality. Mushroom microdoses are more of a personal and "fresh" interaction with the universe. (ID13)
>
> I find that microdosing mushrooms works fine, but LSD microdoses are very uncomfortable as they are too stimulating for me. (ID19)

Reported challenges

Despite the general emphasis on subtle benign effects, the respondents in this study also pointed to a number of challenges associated with microdosing practices. Most commonly reported was the problem of overdosing. Psychedelic drugs are well known for their powerful psychoactive effects, and the resulting state of consciousness is not regarded as compatible with everyday social activities. While there were no reports of accidentally taking a full dose when attempting to microdose, several respondents had unintentionally verged into the terrain of a mini-dose that led to uncomfortable situations:

> I experimented with microdosing mushrooms, but went a bit too far with 0.25 g while at work. I don't know if it was because of the situation, my empty stomach or because I was extra sensitive during that period - but I started tripping quite noticeably! Fortunately it turned out alright. At this level of dosage the peak only lasts for about an hour. (ID25)
>
> I was feeling very tired and had a martial arts class to attend for the first time, so I didn't want to make a bad impression. This was my second time microdosing shrooms, and I dosed around 0.25-0.35 g a few hours before in an attempt to peak well before the class and still just be stimulated and in a good positive mood for it. This backfired massively as I had a large meal around the time of dosing and it only really kicked in once I got to the class. I found it very hard to follow instructions and had a huge body load. (ID5)

Some respondents also found that microdosing could exacerbate certain conditions or symptoms. Benign health effects that users experienced in the early phase of microdosing did in some cases disappear or even reverse themselves after a long period of use.

> One note of caution: if you drink alcohol, don't microdose if you are feeling even slightly hungover, it will get worse, not better. Other than that, be sure to take your first dose on a day where you don't have too much going on as overshooting the mark can be less than productive. (ID33)
>
> I noticed that after a certain point, the benefits fade, and microdosing instead serves to exacerbate my mental health problems. (ID17)

Even when no such adverse effects have been identified, some expressed uneasiness over the fact that the impact of long-term psychedelics microdoses on the brain remains unstudied and unknown:

> Honestly I must admit that it is a bit unnerving to be on the forefront of microdose experimentation. I haven't yet talked to or met anyone who has taken this for as long as I have. (ID38)

A few respondents also mentioned insomnia as a problem, especially if they microdosed late in the day. This was connected to the feeling of overstimulation from LSD microdoses that was reported by several respondents, and both overstimulation and insomnia contributed to a "bad trip" experience reported by one participant who mixed a microdose of LSD with a full dose of cannabis. Another respondent reported that the feeling after taking a microdose reminded him of the early build-up stage of a full trip, which for him was often accompanied by tension.

Discussion

The purpose of this study was to explore how "ordinary" users of psychedelics approach psychedelic microdosing. The selection of users included in this study was not, however, representative of the population of psychedelics users, and the findings of the study therefore have no claim to general validity. Despite this shortcoming, the findings may serve to acquaint researchers with the, as of yet, understudied phenomenon of psychedelic microdosing.

The microdosing practices reported in this study generally conformed in regimen and dose to the recommendations published by Fadiman (2011), although some users experimented with daily microdoses. LSD and psilocybin-containing mushrooms were most commonly used, but some respondents also microdosed a wide range of lesser-known psychedelics and other psychoactive drugs. Respondents for the most part reported what they regarded as positive effects from microdosing, with few side effects. Microdoses most commonly served as mood and cognitive enhancers, allowing people to function at what they felt was a higher level than usual. There are clear parallels between psychedelic microdosing and the use of cognitive enhancement drugs among healthy individuals for performance improvements described by Corazza *et al*. (2014) and Hupli *et al*. (2016), as both forms of drug use can be motivated by a wish for enhanced performance in the workplace or in academic study.

However, there was also a therapeutic motivation for psychedelic microdosing among some of the respondents in this study who suffered from conditions such as anxiety or depression. These findings are congruent with reported effects from full doses of psychedelic drugs on conditions of depression and anxiety (Carhart-Harris & Nutt, 2010; Gasser *et al*., 2013; Griffiths *et al*., 2016; Grob *et al*., 2011; Johnstad, 2015; Ross *et al*., 2016). Reports about the efficacy of microdosing practices for conditions such as substance dependence, OCD, and PTSD also have parallels in research on therapeutic effects from psychedelics in full doses (Abramson, 1967; Bogenschutz *et al*., 2015; Johnson *et al*., 2014; Krebs & Johansen, 2012; Nichols, 2004; Schenberg *et al*., 2014; Thomas *et al*., 2013). It should be noted, however, that in the present study these observations were limited to one or a few individuals. Clinical research on microdosing should probably first look into putative anxiolytic and antidepressive effects, but need not end there.

The lack of a clear distinction between therapy and enhancement that has been pointed to by anthropologists and sociologists who study enhancement technologies (Coveney *et al*., 2011; Hogle, 2005) is echoed in this study. Some respondents pointed to specific deficiencies that their use of psychedelic microdoses was intended to address, but there was an overlap between the use motivated by such therapeutic effects and the use motivated by an effect of enhancement. In either case, the desired effect from microdosing was to be lifted out of a state of relative limitation into a state of higher functioning. The difference was that in therapeutic use, the state of limitation corresponded with a specific medical diagnosis. One respondent explicitly challenged the notion that his "normal" or pre-microdosing state of being deserved the designation "healthy", even though he had not been diagnosed with any specific ailment.

Some respondents experienced no effects from microdosing at all, however, and several others emphasised that, despite their positive experience, microdosing is no miracle cure. There were some indications that psychedelic microdoses might not retain their perceived beneficial effects over longer stretches of time, and that the use should therefore be constrained to phases, which was indeed the most common approach to microdosing among respondents with extensive experience. This reduction of effect over time might limit the medical value of microdosing psychedelics, and would seem to be an important area of investigation for subsequent clinical research of microdosing.

The most commonly reported challenges with microdosing were overdosing and insomnia. Overdosing in this case means going beyond microdose territory into a mini-dose that has some intoxicating effect. Such minidoses are not by themselves overly problematic for experienced psychedelics users, but might have serious negative consequences for users who combine microdosing with work, driving a car, and other activities not compatible with drug intoxication. The overdosing problem applies both to LSD and to psilocybin-containing mushrooms. The former is fully active in doses of a hundred micrograms, and a microdose is often obtained, rather inexactly, by cutting a blotter into separate pieces. Mushrooms for their part may be subject to a natural variation in psilocybin content (Rätsch, 2005). Clinical applications of microdosing could solve this problem by supplying standardised microdoses, but would have to trust their clients not to take several doses at the same time.

The few negative reports about microdosing in this study were not apparently a result of overdosing, nor is there any other obvious explanation for their occurrence. While these negative experiences constitute a minority, it is important to note that some people may experience distinctly unpleasant effects as a result of microdosing. The reported "bad trip" might appear to be a product more of cannabis use than of the LSD microdose, but damage-reduction publications such as *tripsafe.org* often warn that cannabis might potentiate psychedelic drugs.

The question of whether microdosing of psychedelic drugs should be characterised as "abuse", which was Corazza *et al*.'s (2014) label for piracetam use among healthy individuals, or as "functional drug use", which Hupli *et al*. (2016) argued is the best way to understand the use of cognitive enhancement drugs, is not easily answered. Psychedelics are designated as drugs of abuse in most of the world, but there is a substantial research literature that indicates that their use may have therapeutic effect. It is possible that microdosing may allow users to procure some of the perceived positive effects of these drugs while avoiding the problems that may follow from taking them in full doses.

As a social phenomenon, we can perhaps understand psychedelic microdosing in light of Coveney *et al*.'s (2011) observation that the cultural authority of medical experts may be subject to change. Much medical knowledge is now readily available on the Internet, and electronic fora for psychedelic users serve as knowledge repositories that integrate shared user experiences with medical and neuroscientific information. This has resulted in increased knowledge availability (or at least in the perception of increased knowledge availability), which may have caused a corresponding decrease in the cultural authority of medical experts. The growth of microdosing may therefore reflect a social development in which ordinary people use the Internet for medical advice and feel empowered to take personal responsibility for their medication needs, pursuing therapy and enhancement through means that the medical establishment does not recognise and would perhaps frown upon.

There are no published studies on microdosing with which the findings of this study may be compared. The reports of therapy and enhancement, which constitute the majority here, conform to the findings of previously published anecdotal reports (Fadiman, 2011; Solon, 2016; Waldman, 2017), while the reports of no effect or negative effect are, as far as I can determine, without counterpart. This may reflect a bias towards beneficial effects in anecdotal reports, which Partridge *et al*. (2011) found to be a problem for media reports about enhancement drugs, or perhaps it may be that the method used in this study has been more conducive to obtaining balanced information.

There is no way to differentiate between drug effects and positive or negative expectation effects (placebo/nocebo) in these data, but the study affords an understanding of how "ordinary" users of psychedelics approach psychedelic microdosing. Several respondents expressed nuanced views about the relative benefits and disadvantages of microdosing that were not in any obvious manner indebted to placebo or nocebo effects. They also reported discovering specific practices that have worked well for them, compared to others that were found to be ineffectual or subject to negative side effects. Confidence in the reports is therefore increased by their high degree of specificity, as curative or symptom-abating effect was often reported only for one of several drugs that respondents used.

Another overall finding from this study is the value of tapping the psychedelic Internet community for academic studies. It is unknown whether this segment of Internet-active users is representative of the general psychedelic-using population, but the discussion fora frequented by these users are probably among the best recruitment arenas available to researchers. The respondents in this study were reflective, knowledgeable, and fully capable of expressing their views, and their participation would be an asset to any study of psychedelic drug use. It is possible, however, that a less erudite group of psychedelics users would have a less constructive and self-reflective approach to microdosing, and the study has nothing to say about the attractions of microdosing to women. The findings from this study should therefore be taken to reflect the microdosing experiences of a resourceful group of male psychedelic users, and have value primarily to the extent that they may provide subsequent investigations with research questions and hypotheses.

Abstract

Introduction Taking microdoses (a mere fraction of normal doses) of psychedelic substances, such as truffles, recently gained popularity, as it allegedly has multiple beneficial effects including creativity and problem-solving performance, potentially through targeting serotonergic 5-HT$_{2A}$ receptors and promoting cognitive flexibility, crucial to creative thinking. Nevertheless, enhancing effects of microdosing remain anecdotal, and in the absence of quantitative research on microdosing psychedelics, it is impossible to draw definitive conclusions on that matter. Here, our main aim was to quantitatively explore the cognitive-enhancing potential of microdosing psychedelics in healthy adults.

Methods During a microdosing event organized by the Dutch Psychedelic Society, we examined the effects of psychedelic truffles (which were later analyzed to quantify active psychedelic alkaloids) on two creativity-related problem-solving tasks: the Picture Concept Task assessing convergent thinking and the Alternative Uses Task assessing divergent thinking. A short version of the Ravens Progressive Matrices task assessed potential changes in fluid intelligence. We tested once before taking a microdose and once while the effects were expected to be manifested.

Results We found that both convergent and divergent thinking performance was improved after a non-blinded microdose, whereas fluid intelligence was unaffected.

Conclusion While this study provides quantitative support for the cognitive-enhancing properties of microdosing psychedelics, future research has to confirm these preliminary findings in more rigorous placebo-controlled study designs. Based on these preliminary results, we speculate that psychedelics might affect cognitive metacontrol policies by optimizing the balance between cognitive persistence and flexibility. We hope this study will motivate future microdosing studies with more controlled designs to test this hypothesis.

Keywords Microdosing, Psychedelics, Field study, Convergent thinking, Divergent thinking, Creativity

Introduction

Major news outlets throughout the world are reporting on the growing number of professionals using small doses of psychedelics (e.g., magic mushrooms, truffles, or peyote) to boost their productivity and creativity at work. A prominent example is the use of small doses of LSD by employees in Silicon Valley, as a "productivity hack" (Glatter 2015). This emerging phenomenon is referred to as microdosing, with dosages around one tenth of recreational doses. Yet, despite the low dosages, microdosing is still thought to provide a potential boost in cognition according to anecdotal reports (Cooke 2017; Gregorie 2016; Leonard 2015; Sahakian 2017; Senior 2017; Solon 2016). Moderate to large doses of psychedelics induce changes in perception, mood, and overall consciousness, often described as qualitatively similar to deep meditative or transcendental states (Barrett and Griffiths 2017; Barrett *et al*. 2017). If similar, yet substantially more subtle, effects apply to microdosing, this would render microdosing a potentially interesting cognitive enhancer in healthy individuals or even the basis of a treatment strategy to tackle various disorders including depression.

Throughout the 1960s, psychedelics were extensively used at recreational doses in experimental research, clinical settings, and in creative and scientific vocations (Sessa 2008), but were made illegal in most countries worldwide as a reaction to the rising counterculture of the 1960s and failure to establish the clear efficacy of LSD treatment (Oram 2014). Now, after many decades of disregard, psychedelics have started to reappear as a genuine and promising area of research within experimental and clinical psychology, as well as psychiatry. Moreover, certain psychedelics, such as truffles, have regained a legal status in The Netherlands, offering researchers a particularly interesting opportunity to study its effects in a quantitative manner. This is highly desirable, as previous reports have remained anecdotal (Oberhaus 2017) and qualitative at best, often focusing on experiences of elevated feelings of determination, alertness, and energy, improved pattern recognition, as well as strong reductions of depressive feelings (Fadiman and Krob 2017). Qualitative studies based on self-reports are known to suffer from validity problems due to participants' inaccurate memories, differences in vocabulary and verbal skills, and unintentional or willful distortions of subjective experiences (Schwarz 1999).

Nonetheless, existing research with moderate doses of psilocybin shows that psilocybin is a potent neuropharmacological agent with a strong modulatory effect on brain processes (Vollenweider and Kometer 2010). Furthermore, a double-blind placebo-controlled study by Hasler *et al*. (2004a, b) showed that even very low doses of psilocybin (45 µg/kg body weight) were rated clearly psychoactive by most of the volunteers, which indicates that psychedelic effects do not need high doses to be recognized.

Classical psychedelics such as psilocybin (O-phosphoryl4-hydroxy-N, N-dimethyltryptamine), the active compound in psychedelic truffles, exert their primary effects by directly binding to serotonin 2A receptors (5-HT$_{2A}$; Tyl[1] *et al*. 2014). Interestingly, 5-HT$_{2A}$ agonism has been reported to be associated with enhanced cognitive flexibility (Clarke *et al*. 2004, 2007; Boulougouris *et al*. 2008; Kehagia *et al*. 2010), improved associative learning (Harvey 1995, 2003), and hippocampal neurogenesis (Catlow *et al*. 2016) in animals. Additionally, psychedelics have been shown to increase subjective sense of wellbeing, optimism, and openness in humans (Griffiths *et al*. 2006, 2008; MacLean *et al*. 2011). Moreover, multiple clinical trials using moderate to large doses of psychedelics have indicated that psychedelics have anxiolytic, anti-depressant (dos Santos *et al*. 2016; Carhart-Harris *et al*. 2016a, b; Grob *et al*. 2011; Griffiths *et al*. 2016), anticompulsive (Moreno *et al*. 2006), and anti-addictive properties (Bogenschutz *et al*. 2015; Johnson *et al*. 2014; Krebs and Johansen 2012; dos Santos *et al*. 2016). Consequently, the effects of psychedelic substances can be argued to target the serotonergic system and hence be beneficial in situations where there is a need for mental flexibility, or where one needs to break through rigid patterns of thought. In case that future research confirms positive effects of microdosing on brain and cognition, microdosing could become an attractive alternative due to its more subtle nature possibly sparing individuals from the perceptual distortions often reported with moderate or high doses.

Through the alleged benefits in mental flexibility, a promising behavioral target of psychedelics lies in the area of creativity. Creativity is a multilayered phenomenon, commonly defined as the ability to generate ideas, solutions, or products that are both novel and appropriate (e.g., Amabile 1996; Sternberg and Lubart 1999). Creativity is not a unitary function but consists of a number of subcomponents (Wallas 1926) that provide different, to some degree opposing cognitive challenges. It is crucial to distinguish between convergent thinking, which requires identification of a single solution to a well-defined problem (Mednick 1962), and divergent thinking, which requires the collection of many possible solutions to a loosely defined problem (Guilford 1967). An example of convergent thinking task would be to find the one concept that can be meaningfully combined with three other concepts such as "...man," "...market," and "...bowl" (such as "super"), while an example of divergent thinking task would be to list all possible ways in which a brick could be used (for throwing, as a weight, as a weapon, etc.). It has been argued that convergent thinking draws more on the ability to focus exclusively on a given problem (persistence), while divergent thinking draws more on cognitive flexibility (Lippelt *et al*. 2014). However, it is important to point out that all available creativity tasks require the integration of both of these abilities to some degree. Of further importance to our present study is the fact that creative thinking is not a hardwired virtue. Several behavioral studies have shown that the processes underlying creative thinking can be systematically enhanced and impaired by both behavioral interventions, such as meditation, as well as, psychopharmacological agents, as for instance cannabis, tyrosine, and Adderall (e.g., Baas *et al*. 2014; Colzato *et al*. 2015; Farah *et al*. 2009; Kowal *et al*. 2015; Ritter and Mostert 2016; Schafer *et al*. 2012; Zabelina and Robinson 2010; Davis 2009).

Moreover, a recent study conducted by Kuypers *et al*. (2016) investigated the effect of recreational doses of the psychedelic brew Ayahuasca on creativity during two spiritual retreats. They found that divergent thinking performance improved under the influence of Ayahuasca compared to baseline, while convergent thinking performance decreased in comparison to baseline. Although this study may seem to provide a useful starting point, conclusions are hampered by several disadvantages of this drug and the study design. First, dimethyltryptamine (DMT), the active psychedelic compound in Ayahuasca, needs to be combined with monoamine oxidase inhibitors (MAOIs) for its effect to take place. MAOIs are known to have anti-depressant effects on their own, so they represent a possible confound in all Ayahuasca studies (Quitkin *et al*. 1979). Additionally, this implies that the qualitative experience induced by large doses of Ayahuasca and the underlying mechanisms of action are likely to differ substantially from psychedelic experience induced by microdosing for which LSD or psilocybin are commonly used (Callaway and Grob 1998; Riba *et al*. 2006). Indeed, the Ayahuasca brews used in the study of Kuypers *et al*. (2016) induced strong psychedelic experiences, the effects of which are unlikely to be comparable to the effects obtained from microdosing a psychedelic substance. High doses of psychedelics frequently result in disorienting effects in the user, which makes reliable assessment of psychometric task performance difficult during the peak effects of the psychedelic experience (Hollister 1968). Taken altogether, microdosing of psychedelic truffles and related psychoactive substances may thus be more suitable to assess the enhancing effects of psychedelics on human performance.

The current study is the first to experimentally investigate the cognitive-enhancing effects of microdosing on human cognition in a natural setting. We were offered the unique opportunity to quantitatively study the effects of microdosing truffles during microdosing events of the Psychedelic Society of The Netherlands (PSN), a non-laboratory environment. Natural settings like such an event have a number of potential benefits as they are more comparable to situations of real life use than studies in a laboratory environment. The truffle samples, which participants obtained during the microdosing event, were post hoc analyzed, to determine the exact amount of active substance potentially leading to the found effects. The major aim of our study was to study the effects of psychedelic truffles on creative thinking. We assessed convergent and divergent thinking separately, by using the Picture Concept Task (PCT) (Hurks *et al*. 2010; Wechsler 2003) and Guilford's (1967) Alternate Uses Task (AUT), respectively. Given that convergent thinking is correlated with fluid intelligence (e.g., Akbari Chermahini *et al*. 2012), we also employed a short 12-item version of Raven's Progressive Matrices Task (Bilker *et al*. 2012), a standard intelligence test, once before and while the acute effects were expected to take place. Given the effects of large doses of psychedelics on positive mood, trait openness, and assumed cognitive flexibility reflected by psychosis-like symptoms (Carhart-Harris *et al*. 2016a, b), we expected improvements on the AUT after microdosing, as mood and flexibility are two factors that are known to boost divergent thinking (Baas *et al*. 2008; De Dreu *et al*. 2008; Vosburg 1998; Zabelina and Robinson 2010). Due to a lack of relevant previous studies and the subjectivity of self-reports, the effect on convergent thinking was difficult to predict. On the one hand, previous dissociations of convergent and divergent thinking might suggest that convergent thinking is impaired by microdosing - an outcome that could imply that microdosing shifts cognitive control states from persistence to flexibility (Hommel 2015). However, microdosing may also improve both convergent and divergent thinking, suggesting that microdosing improves the interplay between persistence and flexibility. We did not have specific expectations regarding intelligence, but were interested to see whether possible effects on convergent thinking might generalize to performance on the intelligence task or remained more specific.

Methods

Procedure

The experiment was conducted during a microdosing event organized by the Psychedelic Society of the Netherlands (PSN), who provided us with the opportunity to ask participants to take part in the experiment by means of an on-stage presentation. Interested participants were presented with envelopes containing the informed consents. We asked participants to read the provided information carefully, to sign it if they gave permission for their participation and use of their anonymized, coded data, and to subsequently return it back in the envelope. The envelope also included the experimental tasks for the first session as a booklet. However, we stressed participants to not open the booklet until one of the experimenters asked them to turn the first page to prevent premature exposure to the tasks. The experimenters also kept a close eye on the attendees to further ensure participant compliance. Next, all participants were carefully guided through the experimental tasks. Each task was explained in detail by one of the experimenters with the aid of example items, before participants were allowed to perform the task themselves. This was repeated for each of the three tasks. The protocol was approved by the local ethics committee (Leiden University, Institute of Psychology). The experiment consisted of a baseline session before participants had consumed any psychedelics and a second session carried out while participants were under the influence of a microdose of psychedelic truffles. The tasks were conducted in a group setting free from outside distraction during both sessions. Participants' responses were assessed in paper-and-pencil version. The test battery consisted of the Picture Concept Task (PCT) (Wechsler 2003; Hurks *et al*. 2010) to assess convergent thinking, the Alternate Uses Task (AUT) (Guilford 1967) to assess divergent thinking, and a validated short 12-item version of the Raven's Progressive Matrices Task (RPM) (Bilker *et al*. 2012) to test fluid intelligence. While AUT and RPM were presented fully in paper version, PCT stimuli were presented by PowerPoint to insure precise timing of stimuli presentation (further details about the contents of the psychometric tasks are provided under the "Materials" section). Pre- and post-microdosing performance was assessed by administering two different versions of each task, to reduce potential learning effects. Task versions were counterbalanced across sessions and participants.

After finishing the experimental tasks in the first session, participants consumed a microdose of pre-measured psychedelic truffles made available by the PSN. Participants of the workshop agreed to take psychedelic truffles upon their own risk. The PSN did not adhere to any strict guidelines regarding the dosage given to attendees. Nonetheless, they did take the attendees self-reported approximate weight into account in their recommended dosage, by means of subjective evaluations regarding low, average, and high body weight criteria. Attendees judged to have a low body weight were recommended to take 0.22 g of truffles, those with an average body weight 0.33 g, and those with a high body weight were recommended 0.44 g of dried truffles. Moreover, it should be noted that attendees did not have to adhere to the PSN member's recommendation and were free to choose a dose. However, with reference to the existing microdosing guidelines (Fadiman 2011), the doses provided to participants appeared to be in a meaningful range of a microdose. Following the publication of The Psychedelic Explorer's Guide (Fadiman 2011), a microdose should lie around one tenth to one sixteenth of a regular dose. Considering that a recreational dose of truffles is about 10 g of fresh truffles, a microdose would equal 1 g of fresh truffles. As fresh truffles consist of two thirds of water, this results in a weight of 0.33 g of dried truffles. Participants consumed on average 0.37 of dried truffles which is an appropriate amount given the calculation. Additionally, data on participants' height, body weight, and ingested dose of truffles were independently collected by the researchers in order to examine potential dose-dependent effects in the analysis.

Approximately 1.5 h after attendees had consumed the truffles, participants were asked to take part in the second session of the experiment. The 1.5-h time interval was chosen as the effects of truffles are reported to peak around 30-90 min followed by a few hours long plateau of effects before rapidly subsiding back to baseline (Erowid 2017). By choosing this time interval, we could be certain that all participants were tested while the effects of the truffles were still plateauing during the second session. The procedure during the first session was repeated at the second session. Lastly, participants filled in a questionnaire on medical health, psychedelic and general drug use, and general personal information (e.g., gender, age, first language). After testing, we thanked participants for their participation and debriefed them about the purpose of our experiment.

Sample

Out of all 80 attendees at the microdosing event, 38 volunteered in our experiment. Participants indicated that they were healthy, spoke the required languages for performing the experimental tasks, and whether they had prior experience with the use of psychedelic substances. All 38 participants completed the RPM during both sessions. Regarding the PCT, 11 participants had to be excluded from further analysis, either due to incorrect interpretation of the task instructions or because they did not complete the task either for the first or second session. For the AUT, two participants had to be excluded as the experimenters were unable to read the individuals' writing: two due to missing data on the second session and one due to misinterpretation of the task instructions. Importantly, the individuals that were excluded for the AUT and PCT analysis did not overlap. This suggests that exclusion was random and did not depend on a shared trait or state among those who were excluded from the two analyses. Nonetheless, in order to preserve power, we decided to analyze the data separately for each task. This yielded a sample of 38 participants for the analyses of the RPM data, 27 subjects for the PCT analyses, and 33 for the analyses of the AUT data. Table 1 provides an overview of additional descriptive information regarding the sample.

Sample	Age	Gender (M/F)	BMI	Weight (kg)	Prior experience (Y/N)	Ingested dosage (g)
RPM	31.1 (11.49)	23/15	22.5 (4.74)	68.4 (12.81)	36/2	0.37 (0.159)
AUT	30.0 (10.89)	19/14	22.4 (4.92)	67.5 (13.01)	31/2	0.35 (0.142)
PCT	31.5 (12.49)	18/9	22.9 (5.42)	69.3 (13.36)	25/2	0.41 (0.158)

Table 1 Descriptive statistics for the samples used in the three separate analyses. Numbers indicate mean (SD), unless otherwise specified (gender and prior experience)

Truffle analysis

Dried truffle samples of what participants used during the microdosing event (corresponding to 0.22, 0.33, or 0.44 g dry weight) were post hoc analyzed at the University of Chemistry and Technology Prague (UCT; Laboratory of Biologically Active Substances and Forensic Analysis) to determine the exact amount of active substances potentially leading to the found effects. Analytical standards of psilocin, psilocybin, norbaeocystin, and baeocystin were synthesized in-house (purity ≥ 95%) at UCT. The evaluation of the developed analytical method (Hajkova *et al*. 2016) encompassed the determination of Limit of Quantitation (LOQ) and the determination of the applicable concentration range for each compound studied. LOQ was determined as 10 times the ratio of signal to noise. Concentration was determined for each of the truffle samples separately, and each sample was measured twice. The level of the alkaloids was almost identical in all three samples, however, and the differences were lower than the estimated measurement errors when the results from the different samples are averaged. As such, we report the concentrations for the four alkaloids collapsed across the three samples in the results. For the alkaloid concentrations for the three samples separately and further details regarding the methods underlying these analyses, please see Online Resource 1.

Despite psilocybin usually being the most abundant alkaloid in psychedelic truffle psilocin is commonly considered to be responsible for the psychedelic truffles' characterizing psychoactive effects (Gartz *et al*. 1994; Tyl[1] *et al*. 2014). Psilocybin is quickly metabolized into psilocin in the human body through dephosphorylization, thereby limiting psilocybin's direct contribution to the psychoactive effects in humans. Furthermore, we also report the concentrations of baeocystin and norbaeocystin as it has recently been suggested that they could quickly metabolize into corresponding N-demethylated psilocin derivatives upon consumption through similar processes as are at play in the metabolism of psilocybin (Tyl[1] *et al*. 2014).

Instruments

Picture concept task

The PCT (Wechsler 2003; Hurks *et al*. 2010) is a visual creativity task that involves finding a common association between several images. Each trial consists of a matrix of between 2 × 3 to 3 × 4 pictures (see Fig. 1 for an example). The correct solution is a common association between one picture from each row. Thus, a response indicating an association between two pictures from the same row would be incorrect. Because the task presumes there is only one correct solution to each item, the task has been previously used to measure convergent thinking (Hurks *et al*. 2010). Hence, to complete the task, one should converge on the correct solution, while inhibiting inappropriate or less obvious associations and previously attempted yet incorrect solutions.

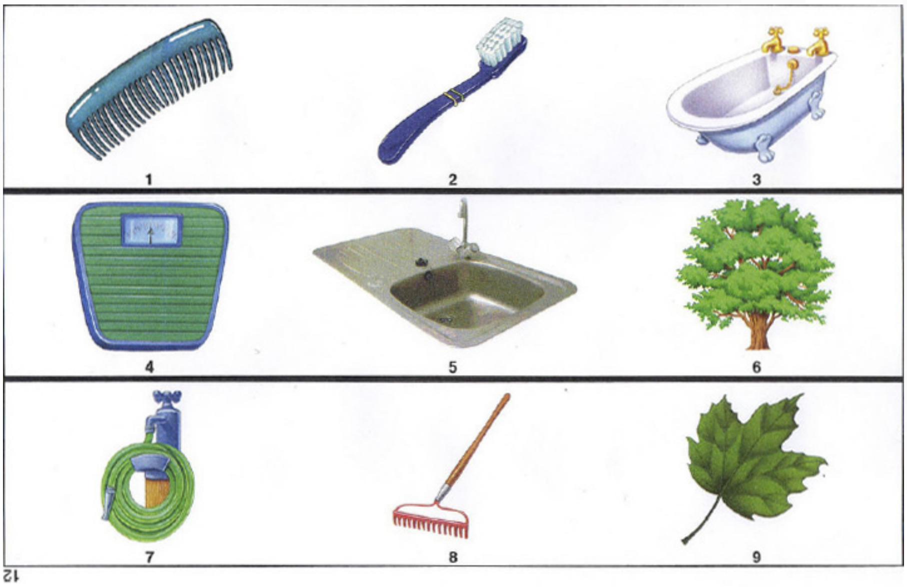

Fig. 1 Example trial from the Picture Concept Task. The subject has to identify the common association between one item from each row.

Participants had 30 s per item to find the solution. Because precise time limit is essential in this task, it was impractical to present the task on paper. Instead, we used a PowerPoint presentation in which the slides (i.e., items) transitioned every 30 s. Participants were instructed to mark and name the common association between the pictures on the PCT response sheet in the booklet (see Fig. 2 for a corresponding answer sheet belonging to the item in Fig. 1). The PCT was scored by summing the number of correct responses.

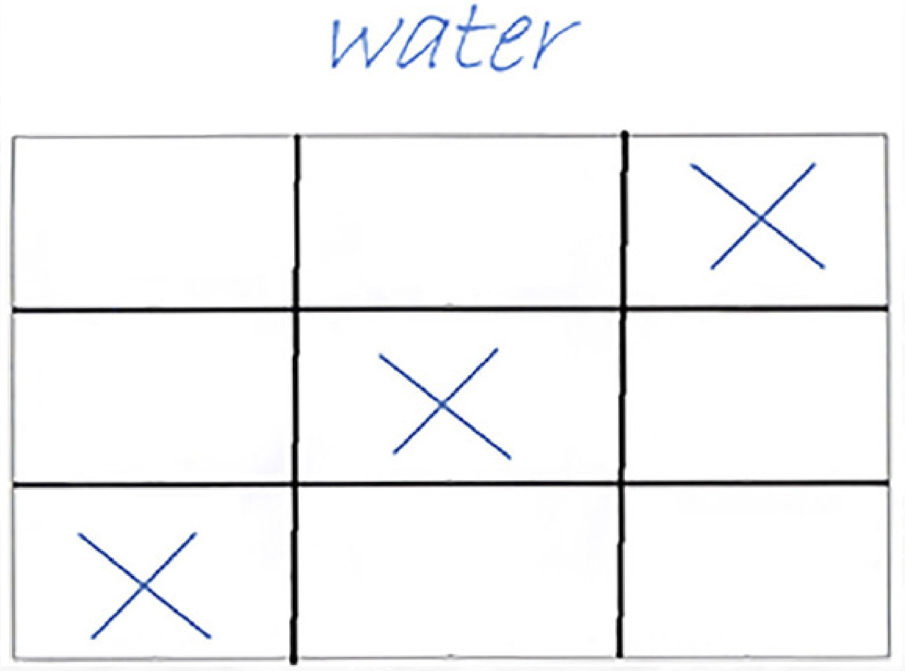

Fig. 2 Illustration of a filled in answer sheet for the items from Fig. 1

Alternate Uses Task

The AUT is commonly used in research on creativity to measure divergent thinking performance (Guilford 1967). During the AUT, subjects are presented with a common household object and asked to think of as many possible uses for the object as they can within a limited amount of time. Within each session of our experiment, participants were either presented with the word Pen or the word Towel and given 5 min (per session) to write down as many possible uses for the object. As common, the AUT was rated according to four different variables:

- Fluency: the total number of responses
- Flexibility: the number of different categories of responses
- Elaboration: how much the person elaborates on their response. Each "elaboration" receives one point. For instance, the response Busing a brick to prevent a door from slamming shut (1), when it is windy (2)" earns two elaboration points.
- Originality: the uniqueness of a response. Originality is calculated by dividing the total number of responses by *all* subjects, once by 5% and once by 1%. Responses that have also been mentioned by 1% or less of the other participants receive two points for originality, while responses that have been mentioned by 1-5% of the participants receive one point for originality. All other responses receive no originality points.

Out of these four, flexibility is the most reliable and theoretically most transparent index of divergent thinking (Akbari Chermahini and Hommel 2010), while fluency neglects the quality of responses and the originality score is highly sample-dependent. As the scoring of AUT variables can be highly subjective, we used the mean score for each of the four measures obtained from two independent raters to increase the reliability of the dependent measures. Reliability scores (Cohen's κ) were very high for fluency (session 1, κ = .970; session 2, κ = .935), fair for flexibility (session 1, κ = .342, session 2, κ = .252), fair to moderate for elaboration (session 1, κ = .231; session 2, κ = .547), and fair for originality (session 1, κ = .254; session 2, κ = .318).

Raven's Progressive Matrices

The RPM was developed by Raven (1938) in order to measure fluid intelligence. We used a shortened 12-item version of the RPM to reduce testing time and participant burden. The 12- item version was developed and validated by Bilker and colleagues (2015) showing high correlations with the full RPM (r = .80 for version A and r =.77 for version B).

In our experiment, the RPM consisted of a series of 2 × 2 or 3 × 3 matrices of pictures in which the lower right picture was always missing. Both horizontally and vertically, a pattern is present in the matrix of pictures allowing the participant to deduce what the missing picture should look like. Underneath each item, six possible solutions were presented and participants marked the correct solution by circling it on paper. While there was no time limit per item, the task had a total time limit of 5 min. Throughout, the RPM items increased in difficulty, but participants were allowed to skip an item in case they felt like they were stuck. However, once they had advanced to a next item (either by skipping or answering), they were no longer allowed to go back to correct earlier responses. The RPM was also scored by summing the number of correct responses.

Analyses

First, separate analyses were run to test for possible interactions between time-point (pre- versus post-truffle ingestion) and participants' body weight, ingested dose, and prior experience with psychedelic substances on the dependent measures. As we did not find any significant interactions, we dropped these factors from any subsequent analyses. To assess changes in fluid intelligence, we performed a paired samples t tests comparing RPM scores at baseline versus RPM scores post ingestion of the truffles in the entire sample. Next, we performed a paired sample t test to compare convergent thinking performance before and after ingestion for the 27 participants for whom we obtained valid data on the PCT for both sessions. To assess microdosing-induced changes in divergent thinking performance, we analyzed the variables obtained from the AUT. Although of main interest were the flexibility and fluency scores, for completeness, we entered all four variables (i.e., fluency, flexibility, elaboration, and originality) as separate dependent measures in one multivariate Repeated Measures ANOVA with time (pre- versus post-ingestion) as the within subject factor. Significant effects in the multivariate ANOVA were followed-up by the appropriate univariate tests. The significance level for all analyses was set to $\alpha = .05$.

Results

Psychedelic content in truffle sample

The Forensic Laboratory of Biologically Active Substances confirmed the presence of the active psychedelic alkaloids in the truffle samples. Quantitative analysis showed the presence of all four investigated alkaloids with predominant levels of psilocybin (see Table 2 for an overview of alkaloid concentrations). The next-most abundant alkaloids were psilocin followed by baeocystin. The concentrations of the four alkaloids were almost identical for all three samples, and the differences were lower than the measurement errors obtained when the data is collapsed across samples.

In this study, we compared task performance before the ingestion of the psychedelic truffles with performance approximately 1.5 h after ingestion (i.e., while the effects of the psychedelic truffles are thought to be fully manifested). Table 3 displays descriptive statistics for both sessions of performance on all dependent measures.

Alkaloid	µg/g (ppm)	SD	Relative SD (%)
Psilocybin	1595	3.75	2
Psilocin	85	0.86	10
Norbaeocystin	8	0.06	7
Baeocystin	31	0.15	5

Table 2 Results of observed analytes averaged over the three dosages

Interaction effects with weight, body mass index, ingested dosage, and prior experience

We tested for possible interaction effects on all dependent measures using Repeated Measures ANOVAs. All *F*s were smaller than 1, except for the interaction with the ingested dosage on the PCT, $F(1, 25) = 1.13$, $p = .299$, and the interactions with prior experience on the PCT, $F(1, 25) = 1.05$, $p = .316$, and RPM, $F(1, 36) = 3.69$, $p = .063$. Nevertheless, these results show that none of the factors significantly interacted with the independent factor time-point and were thus dropped from the final analyses described below.

Fluid intelligence

Comparing fluid intelligence on pre- and post-microdosing using a paired-sample *t* test, we found no difference between the two time-points with respect to the number of correct items on the RPM, $t(37) = 1.00$, $p = .324$, Cohen's $d = .163$.

Convergent thinking Performance on the PCT (number of correct responses) was significantly higher in the second than in the first session, $t(26) = 2.56$, $p = .017$, Cohen's $d = .493$, showing an improvement of convergent thinking.

Measure	Session 1	Session 2
PCT	6.56 (1.601)	7.59 (1.600)
RPM	8.58 (2.238)	8.97 (1.924)
Fluency	14.68 (0.99)	16.70 (1.19)
Flexibility	11.20 (0.80)	12.74 (0.93)
Elaboration	2.18 (0.32)	1.76 (0.28)
Originality	12.36 (1.30)	15.67 (1.45)

Table 3 Descriptive statistics (means (SE)) for the first and second session

Divergent thinking

The four measures of the AUT were analyzed by means of a multivariate Repeated Measures ANOVA. The effect of timepoint was significant, $F(4, 29) = 4.16$, $p = .009$, partial $\eta2 = .365$, due to better performance in the second than the first session. Additional univariate tests showed a significant increase in fluency, $F(1, 32) = 5.59$, $p = .024$, partial $\eta2 = .149$, flexibility, $F(1, 32) = 6.23$, $p = .018$, partial $\eta2 = .163$, and originality scores, $F(1, 32) = 12.03$, $p = .002$, partial $\eta2 = .273$, while the change in elaboration scores failed to reach significance, $F(1, 32) = 2.97$, $p = .226$, partial $\eta2 = .046$.

Discussion

The aim of this study was to explore the effects of microdosing psychedelics on creative problem-solving. We observed an increase in divergent idea generation on the AUT, as evidenced by a significant increase in fluency, flexibility, and originality scores, as well as an increase in convergent thinking on the PCT after intake of a microdose of magic truffles. Given that scores of fluid intelligence did not change between the two measurement time-points, while we did observe change in scores in the creativity domain, it is possible that microdosing targets creativity performance, but not more general analytic cognition. These findings are in line with earlier studies finding positive effects of high doses of psychedelics on creative performance (Harman and Fadiman 1970; Kuypers *et al*. 2016; Zegans *et al*. 1967). In particular, the increase in originality scores on the AUT parallels the increase in originality scores after intake of Ayahuasca reported by Kuypers *et al*. (2016). Taken together, our results suggest that consuming a microdose of truffles allowed participants to create more out-of-the-box alternative solutions for a problem, thus providing preliminary support for the assumption that microdosing improves divergent thinking. Moreover, we also observed an improvement of convergent thinking, that is, increased performance on a task that requires the convergence on one single correct or best solution.

Before continuing to interpret our findings, it is important to consider the implications of the fact that we did not use a control group (for obvious ethical and practical reasons). Given the absence of a control group, we cannot rule out the possibility that changes from the first to the second time-point of measurement are due to the impact of other factors than the microdosed truffles. Two of these factors come to mind. For one, it is possible that increased performance from the first to the second time-point of measurement reflects learning. We consider that possibility not very likely, for three reasons. First, it does not seem to fit with the absence of an improvement for the intelligence measure, even though the Raven task shares many aspects with the PCT and the AUT. Second, studies on convergent thinking have not shown evidence of improved performance with multiple testing - at least if different test items were used. For instance, Colzato *et al*. (2012) had participants perform the Remote Association Task, which can be considered a verbal version of the PCT, three times in different conditions and found neither condition effects nor, and this would be the learning-sensitive test, any interaction between condition and condition order. Third, a recent training study did not reveal any (positive) training effects on AUT performance (Stevenson *et al*. 2014). No effect of eight training sessions was observed for originality; a *negative* training effect was obtained for fluency, and a quadratic effect for flexibility. Both fluency and flexibility measures in fact *decreased* over the first three to four sessions, and only the flexibility measure eventually reached the original baseline in the 8th session. Taken together, we see no empirical support for the possibility that our observations might reflect a learning effect.

For another, it is possible that increased performance from the first to the second time-point reflects an effect of expectation. Expectation effects are widely studied but not well understood (Schwarz *et al*. 2016). Drug-related expectation effects commonly require previous experience with the psychological effects of the respective drug, and it is likely that expectations operate by having been associated with and thus conditioned to stimuli and expectations preceding the actual effect (Schwarz *et al*. 2016). If so, the existence of expectation-based effects does not contradict the existence of real drug effects, as the former in fact rely on the previous experience of the latter. From that perspective, expectation-based effects and drug-induced effects are likely to have comparable impact on psychological functions, presumably even through the same physiological means. Accordingly, while we cannot definitely exclude that the effects we observed actually required the present intake of the drug, they even in the worst case are likely to rely on the previous intake and likely to reflect the effects of that previous intake.

Notwithstanding these caveats, the outcome pattern of the present study is consistent with the idea that microdosing psychedelic substances improves both divergent and convergent thinking. The fact that intelligence was not improved suggests that this effect was rather selective, but the possibility remains that the Raven was less sensitive to the intervention than the other measures were. It is tempting to interpret our observations on divergent thinking in the context of recent suggestions that behavior drawing on flexibility and novelty benefits from a reduction of cognitive top-down control (Cools and D'Esposito 2009, 2011; De Dreu *et al*. 2008; Dreisbach and Goschke 2004; Hommel 2015; Baas *et al*. 2008). According to this view, creativity tasks can be assumed to draw on two distinct, presumably opposing cognitive processes: flexibility is characterized by broadening the attentional scope, which enables individuals to generate many divergent ideas, while persistence is associated with a narrower attentional scope, thus allowing individuals to focus on one creative idea at a time (De Dreu *et al*. 2008; Hommel 2015). Some of the previous empirical dissociations of persistence and flexibility were related to dopaminergic functioning, such as in behavioral genetic studies demonstrating that polymorphisms supporting efficient dopaminergic functioning in the frontal cortex promote persistence while polymorphisms supporting striatal dopaminergic functioning promote flexibility (e.g., Reuter *et al*. 2006; Zabelina *et al*. 2016; for an overview, see Hommel and Colzato 2017). This strengthens the view that frontal and striatal dopaminergic pathways are involved in persistence and flexibility. If we assume that convergent thinking relies more on frontal persistence while divergent thinking relies more on striatal flexibility, our outcomes raise the question how an intervention can manage to improve both convergent and divergent thinking.

Classical hallucinogens, including psilocybin, belong to a group of tryptamines that are thought to exert their primary psychedelic effects through activity at the serotonergic 5- HT2A receptor (Vollenweider and Kometer 2010). Of particular interest in this regard are findings from animal studies showing that 5-HT$_{2A}$ agonist activity (Halberstadt 2015) correlates with an increase in associative learning (Harvey 2003) and improvements in the ability to adapt behavior more flexibly (Bari *et al*. 2010; Boulougouris *et al*. 2008). Moreover, studies in humans have shown that the administration of psychedelics is associated with an increase in the personality trait "Openness" (MacLean *et al*. 2011) and that psychedelics can induce a reduction in symptoms associated with rigid behavior and thought patterns observed in obsessive-compulsive disorder (Moreno *et al*. 2006) and depression (Carhart-Harris *et al*. 2016a, b; Grob *et al*. 2011). Such findings could be tentatively interpreted to imply that psilocybin facilitates more flexible, less constrained kinds of cognition (Carhart-Harris *et al*. 2016a, b).

The 5-HT$_{2A}$ receptors are widely distributed in in the brain and especially so in high-level prefrontal and associative cortex - regions important for learning and memory retrieval, this is likely to have important functional implications (Carhart-Harris and Nutt 2017; Zhang and Stackman 2015). For instance, postsynaptic 5-HT$_{2A}$ receptor activation was shown to be associated with improvements in certain aspects of cognition (Gimpl *et al*. 1979; Harvey 1995, 2003; Harvey *et al*. 2004, 2012; Romano *et al*. 2010; Zhang and Stackman 2015; Zhang *et al*. 2016) as well as an extinction of previously learned response patterns (Zhang *et al*. 2013). However, it is important to note that function of the 5-HT system remains "elusive" given the inherent complexity of the serotonin system and more research has to be conducted in this regard to determine its function (Dayan and Huys 2009; Carhart-Harris and Nutt 2017).

While the assumption of a link between the use of psychedelics and an unconstrained brain state fits well with our findings on divergent thinking, it does not seem to be consistent with our observations on convergent thinking. Microdosing improved performance on the PCT, suggesting that it promotes convergent thinking. Note that this observation contrasts with previous findings by Kuypers *et al*. (2016), who reported that Ayahuasca, also a 5-HT$_{2A}$ agonist, impaired performance on convergent thinking tasks. We believe this discrepancy could be a result of the difference in relative dosage. Kuypers *et al*. (2016) investigated participants after the intake of large doses of Ayahuasca, which is hardly comparable to the microdoses used in the present study. Previous research has shown a relationship between 5-HT$_{2A}$ receptor activity and goal-directed behavior likely due to indirect modulation of DA release (Vollenweider *et al*. 1999; Sakashita *et al*. 2015; Dalley *et al*. 2002; Boureau and Dayan 2011). Dopamine-related adaptive behavior follows an inverted U shape (van Velzen *et al*. 2014), suggesting that smaller doses, such as the microdoses ingested by the participants in our current study, are more likely to move participants towards the most efficient mid-zone of the performance function than higher doses do (see Akbari Chermahini and Hommel 2012, for an application of this rationale on the impact of dopaminergic manipulations on creativity). Indeed, based on self-reports, an online study by Fadiman and Krob (2017) suggests that microdosing could enhance motivation and focus, and reduce distractibility and procrastination - which seems consistent with our observation of improved convergent thinking.

These considerations suggest that microdoses truffle, and perhaps 5-HT$_{2A}$ agonist in general improve processes that are shared by convergent and divergent thinking - irrespective of the existing differences. Indeed, both convergent and divergent thinking tasks rely to some degree on persistence and top-down control and to some degree on unconstrained flexibility (Hommel 2015). While convergent thinking tasks emphasize persistence over flexibility, and divergent-thinking tasks emphasize flexibility over persistence, they both require participants to keep in mind particular search criteria, which they need to test against candidate items in memory (a skill that relies on persistence and top-down control), and to search through novel and often unfamiliar items considered for this test (a skill that relies on flexibility). The tasks thus present participants with a dilemma, which can only be solved by finding a reasonable balance between the antagonistic skills; that is, to be persistent and flexible at the same time, or at least in quick succession. Microdosing therefore might promote the speed or smoothness of switching between persistence and flexibility - an ability that Mekern *et al*. (2019a, b) refer to as "adaptivity." Taken together, whereas large doses of psychedelics might induce an hyper-flexible mode of brain functioning, and possibly a breakdown of control (Carhart-Harris *et al*. 2014), microdoses may be able to drive brain functioning towards an optimal, highly adaptive balance between persistence and flexibility.

Limitations

It is important to consider the limitations of our study. The experiment was carried out "in the field," which offers the benefits of studying more natural effects of microdosing, but also has the disadvantage of allowing less experimental control than in a laboratory setting. We used a quasi-experimental design, which limits some of the conclusions that can be drawn from our study. Neither the participants nor the researchers were blind to the manipulation and, as all participants consumed a microdose of psychedelic truffles, we were unable to collect data from a control group - which in this particular context would have been hard to conceive anyway. Relatedly, the absence of a placebo condition prevented any kind of randomization of the administered substance. Participants were not randomly selected due to the nature of the event, resulting in a self-selection bias, and limiting the generalizability of our findings. While we have argued that previous findings render the possibility of learning effects unlikely, it is also true that we were unable to quantify possible learning effects in the present study. Moreover, the absence of a control group did not allow us to identify and quantify possible placebo/expectation effects. Even though we have argued that this need not undermine our conclusions, future studies should definitely consider expectation/placebo effects, not only as a possible confound but also as a useful replacement of the actual drug. Another possible objection might be that mood might have contributed to our findings. Indeed, it is well known that divergent thinking benefits from positive mood (Ashby *et al*. 1999; Baas *et al*. 2008; Davis 2009), providing a possible confound regarding the effects we observed on our divergent thinking task. However, given that we also found positive effects for convergent thinking, which has not shown to benefit from positive mood, would not fit with a mood-related interpretation. Moreover, the well-established association between serotonin levels and depression (Neumeister 2003; Baldwin and Rudge 1995) suggests that mood should be considered the phenomenological expression of a particular serotonin level (arguably in combination with other factors) rather than an independent factor that can moderate the impact of changes in serotonin levels on cognitive performance. In retrospect, we also acknowledge that perceived strength of drug effect would have been a valuable measure to assess as it could have played some role in our outcome measures.

Furthermore, it has been shown that in contrast, however, positive mood negatively predicts convergent thinking performance, which in our study improved after ingestion of the psychedelic truffles. Future studies should seek to validate our findings using a lab-based randomized double-blind placebo-controlled experimental designs and take the subjective strength of the experience into account as a covariate.

Conclusion

Whereas large doses of psychedelics can introduce a range of undesirable side effects, microdoses of psychedelic substances might prove to be a promising alternative that could eliminate the risks of challenging experiences (sometimes referred to as a "bad trips") while maintaining the potential benefits of psychedelic substances on human emotion and cognition. The current naturalistic study is the first to quantitatively show that microdosing psychedelics could improve creative performance, possibly by means of inducing a state of unconstrained thought allowing for increased novel idea generation. We hope that our findings will stimulate further research into the beneficial effects of microdosing psychedelics. Apart from its benefits as a potential cognitive enhancement technique, microdosing could be further investigated for its therapeutic efficacy as to slow down cognitive decline or help individuals who suffer from rigid thought patterns or behavior such as individuals with depression or obsessive-compulsive disorder.

Acknowledgements We would like to thank the Psychedelic Society of The Netherlands for providing us with the opportunity to do the experiment at one of their events and Eliska Prochazkova for helping carrying out the experiment.
This research was partly funded by an Advanced Grant of the European Research Council (ERC-2015-AdG-694722) to BH, and by the MICR (grant no. VI20172020056) to MK.

Author contributions The study was set up together by all authors, who also contributed to data interpretation and writing the manuscript and approved the final version of the manuscript. LP and DPL had the original idea, carried out the experiment, analyzed the data, and wrote a first draft of the article.

Compliance with ethical standards

Conflict of interest The authors declare that they have no conflict of interest.

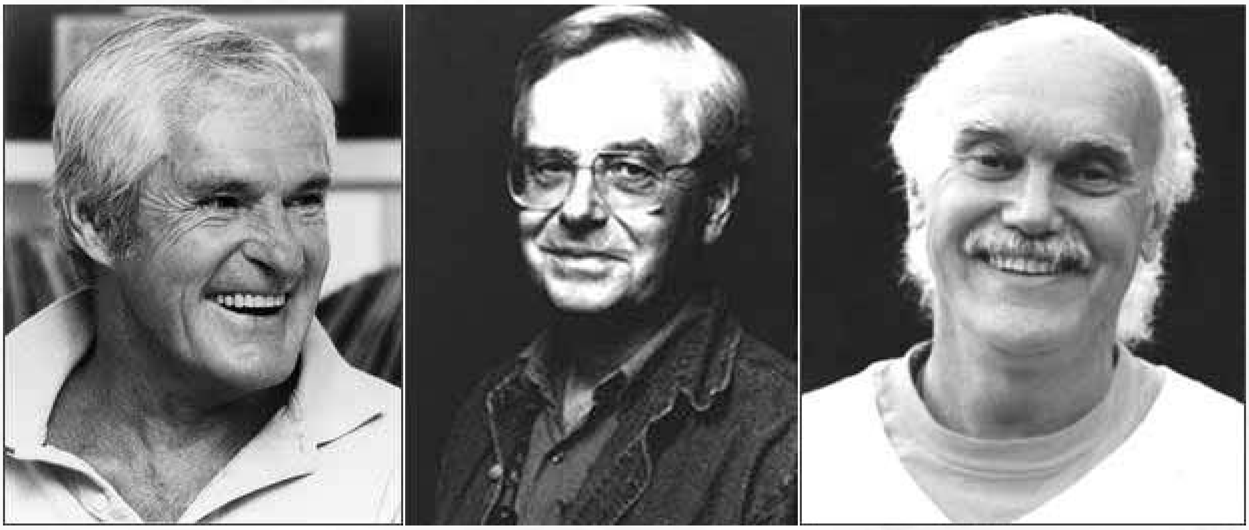
A manual based on the Tibetan Book of the Dead By Timothy Leary, Ph.D., Ralph Metzner, Ph.D., & Richard Alpert, Ph.D.

original source: https://www.erowid.org/archive/hyperreal/drugs/psychedelics/leary/psychedelic.html

The authors were engaged in a program of experiments with LSD and other psychedelic drugs at Harvard University, until sensational national publicity, unfairly concentrating on student interest in the drugs, led to the suspension of the experiments. Since then, the authors have continued their work without academic auspices.



Leary, Metzner, Alpert

Table of Contents:

I. General Introduction
A Tribute to W. Y. Evans-Wentz
A Tribute to Carl G. Jung
A Tribute to Lama Anagarika Govinda
II. The Tibetan Book Of The Dead
First Bardo: The Period Of Ego-Loss Or Non-Game Ecstasy
Part I: The Primary Clear Light Seen At the Moment of Ego-Loss
Part II: The Secondary Clear Light Seen Immediately After Ego-Loss
Second Bardo: The Period Of Hallucinations
Introduction
Explanation of the Second Bardo
The Peaceful Visions
Vision 1: The Source
Vision 2: The Internal Flow of Archetypal Processes
Vision 3: The Fire-Flow of Internal Unity
Vision 4: The Wave-Vibration Structure of External Forms
Vision 5: The Vibratory Waves of External Unity
Vision 6: "The Retinal Circus"
Vision 7: "The Magic Theatre"
The Wrathful Visions
Conclusion Of Second Bardo

Third Bardo: The Period Of Re-Entry
Introduction into Third Bardo
I. General Description of the Third Bardo
II. Re-entry Visions
III. The All-Determining Influence of Thought
IV. Judgment Visions
V. Sexual Visions
VI. Methods for Preventing the Re-Entry
VII. Methods of Choosing the Post-Session Personality
General Conclusion
III. Some Technical Comments About Psychedelic Sessions
1. Use of This Manual
2. Planning a Session
3. Drugs and Dosages
4. Preparation
5. The Setting
6. The Psychedelic Guide
7. Composition of the Group
IV. Instructions For Use During A Psychedelic Session
First Bardo Instructions
Second Bardo Preliminary Instructions
Instructions For Vision 1: The Source
Instructions For Physical Symptoms
Instructions For Vision 2: The Internal Flow Of Archetypal Processes
Instructions For Vision 3: The Fire-Flow Of Internal Unity
Instructions For Vision 4: The Wave-Vibration Structure Of External Forms
Instructions For Vision 5: The Vibratory Waves Of External Unity
Instructions For Vision 6: "The Retinal Circus"
Instructions For Vision 7: "The Magic Theatre"
Instructions For The Wrathful Visions
Third Bardo: Preliminary Instructions
Instructions For Re-Entry Visions
Instructions For The All-Determining Influence Of Thought
Instructions For Judgment Visions
Instructions For Sexual Visions
Four Methods of Preventing Re-entry
First Method: Meditation on the Buddha
Second Method: Meditation on Good Games
Third Method: Meditation on Illusion
Fourth Method: Meditation on the Void
Instructions For Choosing the Post-Session Personality

This version of THE TIBETAN BOOK OF THE DEAD is dedicated,
to
ALDOUS HUXLEY

July 26, 1894 - November 22, 1963 with profound admiration and gratitude.

> "If you started in the wrong way," I said in answer to the investigator's questions, "everything that happened would be a proof of the conspiracy against you. It would all be self-validating. You couldn't draw a breath without knowing it was part of the plot."
>
> "So you think you know where madness lies?"
>
> My answer was a convinced and heartfelt, "Yes."
>
> "And you couldn't control it?"
>
> "No I couldn't control it. If one began with fear and hate as the major premise, one would have to go on the conclusion."
>
> "Would you be able," my wife asked, " to fix your attention on what The Tibetan Book of the Dead calls the Clear Light?"
>
> I was doubtful.
>
> "Would it keep the evil away, if you could hold it? Or would you not be able to hold it?"
>
> I considered the question for some time. "Perhaps," I answered at last, "perhaps I could - but only if there were somebody there to tell me about the Clear Light. One couldn't do it by oneself. That's the point, I suppose, of the Tibetan ritual - somebody sitting there all the time and telling you what's what."
>
> (DOORS OF PERCEPTION, 57-58)

I. General Introduction

A psychedelic experience is a journey to new realms of consciousness. The scope and content of the experience is limitless, but its characteristic features are the transcendence of verbal concepts, of space-time dimensions, and of the ego or identity. Such experiences of enlarged consciousness can occur in a variety of ways: sensory deprivation, yoga exercises, disciplined meditation, religious or aesthetic ecstasies, or spontaneously. Most recently they have become available to anyone through the ingestion of psychedelic drugs such as LSD, psilocybin, mescaline, DMT, etc. [This is the statement of an ideal, not an actual situation, in 1964. The psychedelic drugs are in the United States classified as "experimental" drugs. That is, they are not available on a prescription basis, but only to "qualified investigators." The Federal Food and Drug Administration has defined "qualified investigators" to mean psychiatrists working in a mental hospital setting, whose research is sponsored by either state or federal agencies.]

Of course, the drug dose does not produce the transcendent experience. It merely acts as a chemical key - it opens the mind, frees the nervous system of its ordinary patterns and structures. The nature of the experience depends almost entirely on set and setting. Set denotes the preparation of the individual, including his personality structure and his mood at the time. Setting is physical - the weather, the room's atmosphere; social - feelings of persons present towards one another; and cultural - prevailing views as to what is real. It is for this reason that manuals or guide-books are necessary. Their purpose is to enable a person to understand the new realities of the expanded consciousness, to serve as road maps for new interior territories which modern science has made accessible.

Different explorers draw different maps. Other manuals are to be written based on different models - scientific, aesthetic, therapeutic. The Tibetan model, on which this manual is based, is designed to teach the person to direct and control awareness in such a way as to reach that level of understanding variously called liberation, illumination, or enlightenment. If the manual is read several times before a session is attempted, and if a trusted person is there to remind and refresh the memory of the voyager during the experience, the consciousness will be freed from the games which comprise "personality" and from positive-negative hallucinations which often accompany states of expanded awareness. The Tibetan Book of the Dead was called in its own language the Bardo Thodol, which means "Liberation by Hearing on the After-Death Plane." The book stresses over and over that the free consciousness has only to hear and remember the teachings in order to be liberated.

The Tibetan Book of the Dead is ostensibly a book describing the experiences to be expected at the moment of death, during an intermediate phase lasting forty-nine (seven times seven) days, and during rebirth into another bodily frame. This however is merely the exoteric framework which the Tibetan Buddhists used to cloak their mystical teachings. The language and symbolism of death rituals of Bonism, the traditional pre-Buddhist Tibetan religion, were skillfully blended with Buddhist conceptions. The esoteric meaning, as it has been interpreted in this manual, is that it is death and rebirth that is described, not of the body. Lama Govinda indicates this clearly in his introduction when he writes: "It is a book for the living as well as the dying." The book's esoteric meaning is often concealed beneath many layers of symbolism. It was not intended for general reading. It was designed to be understood only by one who was to be initiated personally by a guru into the Buddhist mystical doctrines, into the pre-mortem-death- rebirth experience. These doctrines have been kept a closely guarded secret for many centuries, for fear that naive or careless application would do harm. In translating such an esoteric text, therefore, there are two steps: one, the rendering of the original text into English; and two, the practical interpretation of the text for its uses. In publishing this practical interpretation for use in the psychedelic drug session, we are in a sense breaking with the tradition of secrecy and thus contravening the teachings of the lama-gurus.

However, this step is justified on the grounds that the manual will not be understood by anyone who has not had a consciousness-expanding experience and that there are signs that the lamas themselves, after their recent diaspora, wish to make their teachings available to a wider public.

Following the Tibetan model then, we distinguish three phases of the psychedelic experience. The first period (Chikhai Bardo) is that of complete transcendence - beyond words, beyond space-time, beyond self. There are no visions, no sense of self, no thoughts. There are only pure awareness and ecstatic freedom from all game (and biological) involvements. ["Games" are behavioral sequences defined by roles, rules, rituals, goals, strategies, values, language, characteristic space-time locations and characteristic patterns of movement. Any behavior not having these nine features is non- game: this includes physiological reflexes, spontaneous play, and transcendent awareness.] The second lengthy period involves self, or external game reality (Chonyid Bardo) - in sharp exquisite clarity or in the form of hallucinations (karmic apparitions). The final period (Sidpa Bardo) involves the return to routine game reality and the self. For most persons the second (aesthetic or hallucinatory) stage is the longest. For the initiated the first stage of illumination lasts longer. For the unprepared, the heavy game players, those who anxiously cling to their egos, and for those who take the drug in a non-supportive setting, the struggle to regain reality begins early and usually lasts to the end of their session.

Words like these are static, whereas the psychedelic experience is fluid and ever-changing. Typically the subject's consciousness flicks in and out of these three levels with rapid oscillations. One purpose of this manual is to enable the person to regain the transcendence of the First Bardo and to avoid prolonged entrapments in hallucinatory or ego-dominated game patterns.

The Basic Trusts and Beliefs. You must be ready to accept the possibility that there is a limitless range of awareness for which we now have no words; that awareness can expand beyond range of your ego, your self, your familiar identity, beyond everything you have learned, beyond your notions of space and time, beyond the differences which usually separate people from each other and from the world around them.

You must remember that throughout human history, millions have made this voyage. A few (whom we call mystics, saints or buddhas) have made this experience endure and have communicated it to their fellow men.

You must remember, too, that the experience is safe (at the very worst, you will end up the same person who entered the experience), and that all of the dangers which you have feared are unnecessary productions of your mind. Whether you experience heaven or hell, remember that it is your mind which creates them. Avoid grasping the one or fleeing the other. Avoid imposing the ego game on the experience.

You must try to maintain faith and trust in the potentiality of your own brain and the billion-year-old life process. With you ego left behind you, the brain can't go wrong.

Try to keep the memory of a trusted friend or a respected person whose name can serve as a guide and protection.

Trust your divinity, trust your brain, trust your companions.

Whenever in doubt, turn off your mind, relax, float downstream.

After reading this guide, the prepared person should be able, at the very beginning of his experience, to move directly to a state of non-game ecstasy and deep revelation. But if you are not well prepared, or if there is game distraction around you, you will find yourself dropping back. If this happens, then the instructions in Part IV should help you regain and maintain liberation.

"Liberation in this context does not necessarily imply (especially in the case of the average person) the Liberation of Nirvana, but chiefly a liberation of the 'life-flux' from the ego, in such a manner as will afford the greatest possible consciousness and consequent happy rebirth. Yet for the very experienced and very highly efficient person, the [same] esoteric process of Transference [Readers interested in a more detailed discussion of the process of "Transference" are referred to Tibetan Yoga and Secret Doctrines, edited by W. Y. Evans-Wentz, Oxford University Press, 1958.] can be, according to the lama-gurus, so employed as to prevent any break in the flow of the stream of consciousness, from the moment of the ego-loss to the moment of a conscious rebirth (eight hours later). Judging from the translation made by the late Lama Kazi Dawa-Samdup, of an old Tibetan manuscript containing practical directions for ego-loss states, the ability to maintain a non-game ecstasy throughout the entire experience is possessed only by persons trained in mental concentration, or one-pointedness of mind, to such a high degree of proficiency as to be able to control all the mental functions and to shut out the distractions of the outside world." (Evans-Wentz, p. 86, note 2)

This manual is divided into four parts. The first part is introductory. The second is a step-by-step description of a psychedelic experience based directly on the Tibetan Book of the Dead. The third part contains practical suggestions on how to prepare for and conduct a psychedelic session. The fourth part contains instructive passages adapted from the Bardo Thodol, which may be read to the voyager during this session, to facilitate the movement of consciousness.

In the remainder of this introductory section, we review three commentaries on the Tibetan Book of the Dead, published with the Evans- Wentz edition. These are the introduction by Evans-Wentz himself, the distinguished translator-editor of four treatises on Tibetan mysticism; the commentary by Carl Jung, the Swiss psychoanalyst; and by Lama Govinda, and initiate of one of the principle Buddhist orders of Tibet.

A Tribute to W. Y. Evans-Wentz

"Dr. Evans-Wentz, who literally sat at the feet of a Tibetan lama for years, in order to acquire his wisdom ... not only displays a deeply sympathetic interest in those esoteric doctrines so characteristic of the genius of the East, but likewise possesses the rare faculty of making them more or less intelligible to the layman." [Quoted from a book review in Anthropology on the back of the Oxford University Press edition of The Tibetan Book of the Dead.]

W. Y. Evans-Wentz is a great scholar who devoted his mature years to the role of bridge and shuttle between Tibet and the west: like an RNA molecule activating the latter with the coded message of the former. No greater tribute could be paid to the work of this academic liberator than to base our psychedelic manual upon his insights and to quote directly his comments on "the message of this book."

The message is, that the Art of Dying is quite as important as the Art of Living (or of Coming into Birth), of which it is the complement and summation; that the future of being is dependent, perhaps entirely, upon a rightly controlled death, as the second part of this volume, setting forth the Art of Reincarnating, emphasizes.

The Art of Dying, as indicated by the death-rite associated with initiation into the Mysteries of Antiquity, and referred to by Apuleius, the Platonic philosopher, himself an initiate, and by many other illustrious initiates, and as The Egyptian Book of the Dead suggests, appears to have been far better known to the ancient peoples inhabiting the Mediterranean countries than it is now by their descendants in Europe and the Americas.

To those who had passed through the secret experiencing of pre-mortem death, right dying is initiation, conferring, as does the initiatory death-rite, the power to control consciously the process of death and regeneration. (Evans-Wentz, p. xiii-xiv)

The Oxford scholar, like his great predecessor of the eleventh century, Marpa ("The Translator"), who rendered Indian Buddhist texts into Tibetan, thereby preserving them from extinction, saw the vital importance of these doctrines and made them accessible to many. The "secret" is no longer hidden: "the art of dying is quite as important as the art of living."

A Tribute to Carl G. Jung

Psychology is the systematic attempt to describe and explain man's behavior, both conscious and non-conscious. The scope of study is broad - covering the infinite variety of human activity and experience; and it is long - tracing back through the history of the individual, through the history of his ancestors, back through the evolutionary vicissitudes and triumphs which have determined the current status of the species. Most difficult of all, the scope of psychology is complex, dealing as it does with processes which are ever-changing.

Little wonder that psychologists, in the face of such complexity, escape into specialization and parochial narrowness.

A psychology is based on the available data and the psychologists' ability and willingness to utilize them. The behaviorism and experimentalism of twentieth-century western psychology is so narrow as to be mostly trivial. Consciousness is eliminated from the field of inquiry. Social application and social meaning are largely neglected. A curious ritualism is enacted by a priesthood rapidly growing in power and numbers.

Eastern psychology, by contrast, offers us a long history of detailed observation and systematization of the range of human consciousness along with an enormous literature of practical methods for controlling and changing consciousness. Western intellectuals tend to dismiss Oriental psychology. The theories of consciousness are seen as occult and mystical. The methods of investigating consciousness change, such as meditation, yoga, monastic retreat, and sensory deprivation, and are seen as alien to scientific investigation. And most damning of all in the eyes of the European scholar, is the alleged disregard of eastern psychologies for the practical, behavioral and social aspects of life. Such criticism betrays limited concepts and the inability to deal with the available historical data on a meaningful level. The psychologies of the east have always found practical application in the running of the state, in the running of daily life and family. A wealth of guides and handbooks exists: the Book of Tao, the Analects of Confucius, the Gita, the I Ching, The Tibetan Book of the Dead, to mention only the best-known.

Eastern psychology can be judged in terms of the use of available evidence. The scholars and observers of China, Tibet, and India went as far as their data allowed them. They lacked the findings of modern science and so their metaphors seem vague and poetic. Yet this does not negate their value. Indeed, eastern philosophic theories dating back four thousand years adapt readily to the most recent discoveries of nuclear physics, biochemistry, genetics, and astronomy.

A major task of any present day psychology - eastern or western - is to construct a frame of reference large enough to incorporate the recent findings of the energy sciences into a revised picture of man.

Judged against the criterion of the use of available fact, the greatest psychologists of our century are William James and Carl Jung. [To properly compare Jung with Sigmund Freud we must look at the available data which each man appropriated for his explorations. For Freud it was Darwin, classical thermodynamics, the Old Testament, Renaissance cultural history, and most important, the close overheated atmosphere of the Jewish family. The broader scope of Jung's reference materials assures that his theories will find a greater congeniality with recent developments in the energy sciences and the evolutionary sciences.] Both of these men avoided the narrow paths of behaviorism and experimentalism. Both fought to preserve experience and consciousness as an area of scientific research. Both kept open to the advance of scientific theory and both refused to shut off eastern scholarship from consideration.

Jung used for his source of data that most fertile source - the internal. He recognized the rich meaning of the eastern message; he reacted to that great Rorshach inkblot, the Tao Te Ching. He wrote perceptive brilliant forewords to the I Ching, to the Secret of the Golden Flower, and struggled with the meaning of The Tibetan Book of the Dead. "For years, ever since it was first published, the Bardo Thodol has been my constant companion, and to it I owe not only many stimulating ideas and discoveries, but also many fundamental insights... Its philosophy contains the quintessence of Buddhist psychological criticism; and, as such, one can truly say that it is of an unexampled superiority."

The Bardo Thodol is in the highest degree psychological in its outlook; but, with us, philosophy and theology are still in the mediaeval, pre-psychological stage where only the assertions are listened to, explained, defended, criticized and disputed, while the authority that makes them has, by general consent, been deposed as outside the scope of discussion.

Metaphysical assertions, however, are statements of the psyche, and are therefore psychological. To the Western mind, which compensates its well- known feelings of resentment by a slavish regard for "rational" explanations, this obvious truth seems all too obvious, or else it is seen as an inadmissible negation of metaphysical "truth." Whenever the Westerner hears the word "psychological," it always sounds to him like "only psychological."

Jung draws upon Oriental conceptions of consciousness to broaden the concept of "projection":

Not only the "wrathful" but also the "peaceful" deities are conceived as sangsaric projections of the human psyche, an idea that seems all too obvious to the enlightened European, because it reminds him of his own banal simplifications. But though the European can easily explain away these deities as projections, he would be quite incapable of positing them at the same time as real. The Bardo Thodol can do that, because, in certain of its most essential metaphysical premises, it has the enlightened as well as the unenlightened European at a disadvantage. The ever-present, unspoken assumption of the Bardo Thodol is the anti-nominal character of all metaphysical assertions, and also the idea of the qualitative difference of the various levels of consciousness and of the metaphysical realities conditioned by them. The background of this unusual book is not the niggardly European "either-or," but a magnificently affirmative "both-and." This statement may appear objectionable to the Western philosopher, for the West loves clarity and unambiguity; consequently, one philosopher clings to the position, "God is," while another clings equally fervently to the negation, "God is not."

Jung clearly sees the power and breadth of the Tibetan model but occasionally he fails to grasp its meaning and application. Jung, too, was limited (as we all are) to the social models of his tribe. He was a psychoanalyst, the father of a school. Psychotherapy and psychiatric diagnosis were the two applications which came most naturally to him.

Jung misses the central concept of the Tibetan book. This is not (as Lama Govinda reminds us) a book of the dead. It is a book of the dying; which is to say a book of the living; it is a book of life and how to live. The concept of actual physical death was an exoteric facade adopted to fit the prejudices of the Bonist tradition in Tibet. Far from being an embalmers' guide, the manual is a detailed account of how to lose the ego; how to break out of personality into new realms of consciousness; and how to avoid the involuntary limiting processes of the ego; how to make the consciousness-expansion experience endure in subsequent daily life.

Jung struggles with this point. He comes close but never quite clinches it. He had nothing in his conceptual framework which could make practical sense out of the ego-loss experience.

The Tibetan Book of the Dead, or the Bardo Thodol, is a book of instructions for the dead and dying. Like The Egyptian Book of the Dead it is meant to be a guide for the dead man during the period of his Bardo existence... .

In this quote Jung settles for the exoteric and misses the esoteric. In a later quote he seems to come closer:

... the instruction given in the Bardo Thodol serves to recall to the dead man the experience of his initiation and the teachings of his guru, for the instruction is, at bottom, nothing less than an initiation of the dead into the Bardo life, just as the initiation of the living was a preparation for the Beyond. Such was the case, at least, with all the mystery cults in ancient civilizations from the time of the Egyptian and Eleusinian mysteries. In the initiation of the living, however, this "Beyond" is not a world beyond death, but a reversal of the mind's intentions and outlook, a psychological "Beyond" or, in Christian terms, a "redemption" from the trammels of the world and of sin. Redemption is a separation and deliverance from an earlier condition of darkness and unconsciousness, and leads to a condition of illumination and releasedness, to victory and transcendence over everything "given."

Thus far the Bardo Thodol is, as Dr. Evans-Wentz also feels, an initiation process whose purpose it is to restore to the soul the divinity it lost at birth.

In still another passage Jung continues the struggle but misses again:

Nor is the psychological use we make of it (the Tibetan Book) anything but a secondary intention, though one that is possibly sanctioned by lamaist custom. The real purpose of this singular book is the attempt, which must seem very strange to the educated European of the twentieth century, to enlighten the dead on their journey through the regions of the Bardo. The Catholic Church is the only place in the world of the white man where any provision is made for the souls of the departed.

In the summary of Lama Govinda's comments which follow we shall see that the Tibetan commentator, freed from the European concepts of Jung, moves directly to the esoteric and practical meaning of the Tibetan book.

In his autobiography (written in 1960) Jung commits himself wholly to the inner vision and to the wisdom and superior reality of internal perceptions. In 1938 (when his Tibetan commentary was written) he was moving in this direction but cautiously and with the ambivalent reservations of the psychiatrist cum mystic.

The dead man must desperately resist the dictates of reason, as we understand it, and give up the supremacy of egohood, regarded by reason as sacrosanct. What this means in practice is complete capitulation to the objective powers of the psyche, with all that this entails; a kind of symbological death, corresponding to the Judgement of the Dead in the Sidpa Bardo. It means the end of all conscious, rational, morally responsible conduct of life, and a voluntary surrender to what the Bardo Thodol calls "karmic illusion." Karmic illusion springs from belief in a visionary world of an extremely irrational nature, which neither accords with nor derives from our rational judgments but is the exclusive product of uninhibited imagination. It is sheer dream or "fantasy," and every well-meaning person will instantly caution us against it; nor indeed can one see at first sight what is the difference between fantasies of this kind and the phantasmagoria of a lunatic. Very often only a slight abaissement du niveau mental is needed to unleash this world of illusion. The terror and darkness of this moment has its equivalent in the experiences described in the opening sections of the Sidpa Bardo. But the contents of this Bardo also reveal the archetypes, the karmic images which appear first in their terrifying form. The Chonyid state is equivalent to a deliberately induced psychosis... .

The transition, then, from the Sidpa state to the Chonyid state is a dangerous reversal of the aims and intentions of the conscious mind. It is a sacrifice of the ego's stability and a surrender to the extreme uncertainty of what must seem like a chaotic riot of phantasmal forms. When Freud coined the phrase that the ego was "the true seat of anxiety," he was giving voice to a very true and profound intuition. Fear of self-sacrifice lurks deep in every ego, and this fear is often only the precariously controlled demand of the unconscious forces to burst out in full strength. No one who strives for selfhood (individuation) is spared this dangerous passage, for that which is feared also belongs to the wholeness of the self - the sub-human, or supra-human, world of psychic "dominants" from which the ego originally emancipated itself with enormous effort, and then only partially, for the sake of a more or less illusory freedom. This liberation is certainly a very necessary and very heroic undertaking, but it represents nothing final: it is merely the creation of a subject, who, in order to find fulfillment, has still to be confronted by an object. This, at first sight, would appear to be the world, which is swelled out with projections for that very purpose. Here we seek and find our difficulties, here we seek and find our enemy, here we seek and find what is dear and precious to us; and it is comforting to know that all evil and all good is to be found out there, in the visible object, where it can be conquered, punished, destroyed or enjoyed. But nature herself does not allow this paradisal state of innocence to continue for ever. There are, and always have been, those who cannot help but see that the world and its experiences are in the nature of a symbol, and that it really reflects something that lies hidden in the subject himself, in his own transubjective reality. It is from this profound intuition, according to lamaist doctrine, that the Chonyid state derives its true meaning, which is why the Chonyid Bardo is entitled "The Bardo of the Experiencing of Reality."

The reality experienced in the Chonyid state is, as the last section of the corresponding Bardo teaches, the reality of thought. The "thought-forms" appear as realities, fantasy takes on real form, and the terrifying dream evoked by karma and played out by the unconscious "dominants" begins.

Jung would not have been surprised by professional and institutional antagonism to psychedelics. He closes his Tibetan commentary with a poignant political aside:

The Bardo Thodol began by being a "closed" book, and so it has remained, no matter what kind of commentaries may be written upon it. For it is a book that will only open itself to spiritual understanding and this is a capacity which no man is born with, but which he can only acquire through special training and special experience. It is good that such to all intents and purposes "useless" books exist. They are meant for those "queer folk" who no longer set much store by the uses, aims, and meaning of present-day "civilization."

To provide "special training" for the "special experience" provided by psychedelic materials is the purpose of this version of The Tibetan Book of the Dead.

A Tribute to Lama Anagarika Govinda

In the preceding section the point was made that eastern philosophy and psychology - poetic, indeterministic, experiential, inward-looking, vaguely evolutionary, open-ended - is more easily adapted to the findings of modern science than the syllogistic, certain, experimental, externalizing logic of western psychology. The latter imitates the irrelevant rituals of the energy sciences but ignores the data of physics and genetics, the meanings and implications.

Even Carl Jung, the most penetrating of the western psychologists, failed to understand the basic philosophy of the Bardo Thodol.

Quite in contrast are the comments on the Tibetan manual by Lama Anagarika Govinda.

His opening statement at first glance would cause a Judaeo-Christian psychologist to snort in impatience. But a close look at these phrases reveals that they are the poetic statement of the genetic situation as currently described by biochemists and DNA researchers.

It may be argued that nobody can talk about death with authority who has not died; and since nobody, apparently, has ever returned from death, how can anybody know what death is, or what happens after it?

The Tibetan will answer: "There is not one person, indeed, not one living being, that has not returned from death. In fact, we all have died many deaths, before we came into this incarnation. And what we call birth is merely the reverse side of death, like one of the two sides of a coin, or like a door which we call 'entrance' from outside and 'exit' from inside a room."

The lama then goes on to make a second poetic comment about the potentialities of the nervous system, the complexity of the human cortical computer.

It is much more astonishing that not everybody remembers his or her previous death; and, because of this lack of remembering, most persons do not believe there was a previous death. But, likewise, they do not remember their recent birth - and yet they do not doubt that they were recently born. They forget that active memory is only a small part of our normal consciousness, and that our subconscious memory registers and preserves every past impression and experience which our waking mind fails to recall.

The lama then proceeds to slice directly to the esoteric meaning of the Bardo Thodol - that core meaning which Jung and indeed most European Orientalists have failed to grasp.

For this reason, the Bardo Thodol, the Tibetan book vouchsafing liberation from the intermediate state between life and re-birth, - which state men call death, - has been couched in symbolical language. It is a book which is sealed with the seven seals of silence, - not because its knowledge would be misunderstood, and, therefore, would tend to mislead and harm those who are unfitted to receive it. But the time has come to break the seals of silence; for the human race has come to the juncture where it must decide whether to be content with the subjugation of the material world, or to strive after the conquest of the spiritual world, by subjugating selfish desires and transcending self-imposed limitations.

The lama next describes the effects of consciousness-expansion techniques. He is talking here about the method he knows-the Yogic-but his words are equally applicable to psychedelic experience.

There are those who, in virtue of concentration and other yogic practices, are able to bring the subconscious into the realm of discriminative consciousness and, thereby, to draw upon the unrestricted treasury of subconscious memory, wherein are stored the records not only of our past lives but the records of the past of our race, the past of humanity, and of all pre-human forms of life, if not of the very consciousness that makes life possible in this universe.

If, through some trick of nature, the gates of an individual's subconsciousness were suddenly to spring open, the unprepared mind would be overwhelmed and crushed. Therefore, the gates of the subconscious are guarded, by all initiates, and hidden behind the veil of mysteries and symbols.

In a later section of his foreword the lama presents a more detailed elaboration of the inner meaning of the Thodol.

If the Bardo Thodol were to be regarded as being based merely upon folklore, or as consisting of religious speculation about death and a hypothetical after-death state, it would be of interest only to anthropologists and students of religion. But the Bardo Thodol is far more. It is a key to the innermost recesses of the human mind, and a guide for initiates, and for those who are seeking the spiritual path of liberation.

Although the Bardo Thodol is at present time widely used in Tibet as a breviary, and read or recited on the occasion of death, - for which reason it has been aptly called "The Tibetan Book of the Dead" - one should not forget that it was originally conceived to serve as a guide not only for the dying and the dead, but for the living as well. And herein lies the justification for having made The Tibetan Book of the Dead accessible to a wider public.

Notwithstanding the popular customs and beliefs which, under the influence of age-old traditions of pre-uddhist origin, have grown around the profound revelations of the Bardo Thodol, it has value only for those who practice and realize its teaching during their life-time.

There are two things which have caused misunderstanding. One is that the teachings seem to be addressed to the dead or the dying; the other that the title contains the expression "Liberation through Hearing" (in Tibetan, Thos-grol). As a result, there has arisen the belief that it is sufficient to read or recite the Bardo Thodol in the presence of a dying person, or even of a person who has just died, in order to effect his or her liberation.

Such misunderstanding could only have arisen among those who do not know that it is one of the oldest and most universal practices for the initiate to go through the experience of death before he can be spiritually reborn. Symbolically he must die to his past, and to his old ego, before he can take his place in the new spiritual life into which he has been initiated.

The dead or the dying person is addressed in the Bardo Thodol mainly for three reasons: (1) the earnest practitioner of these teachings should regard every moment of his or her life as if it were the last; (2) when a follower of these teachings is actually dying, he or she should be reminded of the experiences at the time of initiation, or of the words (or mantra) of the guru, especially if the dying one's mind lacks alertness during the critical moments; and (3) one who is still incarnate should try to surround the person dying, or just dead, with loving and helpful thoughts during the first stages of the new, or afterdeath, state of existence, without allowing emotional attachment to interfere or to give rise to a state of morbid mental depression. Accordingly, one function of the Bardo Thodol appears to be more to help those who have been left behind to adopt the right attitude towards the dead and towards the fact of death than to assist the dead, who, according to Buddhist belief, will not deviate from their own karmic path... .

This proves that we have to do here with life itself and not merely with a mass for the dead, to which the Bardo Thodol was reduced in later times... .

Under the guise of a science of death, the Bardo Thodol reveals the secret of life; and therein lies its spiritual value and its universal appeal.

Here then is the key to a mystery which has been passed down for over 2,500 years - the consciousness-expansion experience - the pre-mortem death and rebirth rite. The Vedic sages knew the secret; the Eleusinian initiates knew it; the Tantrics knew it. In all their esoteric writings they whisper the message: it is possible to cut beyond ego-consciousness, to tune in on neurological processes which flash by at the speed of light, and to become aware of the enormous treasury of ancient racial knowledge welded into the nucleus of every cell in your body.

Modern psychedelic chemicals provide a key to this forgotten realm of awareness. But just as this manual without the psychedelic awareness is nothing but an exercise in academic Tibetology, so, too, the potent chemical key is of little value without the guidance and the teachings.

Westerners do not accept the existence of conscious processes for which they have no operational term. The attitude which is prevalent is: - if you can't label it, and if it is beyond current notions of space-time and personality, then it is not open for investigation. Thus we see the ego-loss experience confused with schizophrenia. Thus we see present-day psychiatrists solemnly pronouncing the psychedelic keys as psychosis-producing and dangerous.

The new visionary chemicals and the pre-mortem-death-rebirth experience may be pushed once again into the shadows of history. Looking back, we remember that every middle-eastern and European administrator (with the exception of certain periods in Greece and Persia) has, during the last three thousand years, rushed to pass laws against any emerging transcendental process, the pre-mortem-death-rebirth session, its adepts, and any new method of consciousness-expansion.

The present moment in human history (as Lama Govinda points out) is critical. Now, for the first time, we possess the means of providing the enlightenment to any prepared volunteer. (The enlightenment always comes, we remember, in the form of a new energy process, a physical, neurological event.) For these reasons we have prepared this psychedelic version of The Tibetan Book of the Dead. The secret is released once again, in a new dialect, and we sit back quietly to observe whether man is ready to move ahead and to make use of the new tools provided by modern science.

II. The Tibetan Book Of The Dead

First Bardo: The Period Of Ego-Loss Or Non-Game Ecstasy (Chikhai Bardo)

Part I: The Primary Clear Light Seen At the Moment of Ego-Loss

All individuals who have received the practical teachings of this manual will, if the text be remembered, be set face to face with the ecstatic radiance and will win illumination instantaneously, without entering upon hallucinatory struggles and without further suffering on the age-long pathway of normal evolution which traverses the various worlds of game existence.

This doctrine underlies the whole of the Tibetan model. Faith is the first step on the "Secret Pathway." Then comes illumination and with it certainty; and when the goal is won, emancipation. Success implies very unusual preparation in consciousness expansion, as well as much calm, compassionate game playing (good karma) on the part of the participant. If the participant can be made to see and to grasp the idea of the empty mind as soon as the guide reveals it - that is to say, if he has the power to die consciously - and, at the supreme moment of quitting the ego, can recognize the ecstasy which will dawn upon him then, and become one with it, all game bonds of illusion are broken asunder immediately: the dreamer is awakened into reality simultaneously with the mighty achievement of recognition.

It is best if the guru (spiritual teacher), from whom the participant received guiding instructions, is present, but if the guru cannot be present, then another experienced person; or it the latter is also unavailable, then a person whom the participant trusts should be available to read this manual without imposing any of his own games. Thereby the participant will be put in mind of what he had previously heard of the experience and will at once come to recognize the fundamental Light and undoubtedly obtain liberation.

Liberation is the nervous system devoid of mental-conceptual activity. [Realization of the Voidness, the Unbecome, the Unborn, the Unmade, the Unformed, implies Buddhahood, Perfect Enlightenment - the state of the divine mind of the Buddha. It may be helpful to remember that this ancient doctrine is not in conflict with modern physics. The theoretical physicist and cosmologist, George Gamow, presented in 1950 a viewpoint which is close to the phenomenological experience described by the Tibetan lamas.

If we imagine history running back in time, we inevitably come to the epoch of the "big squeeze" with all the galaxies, stars, atoms and atomic nuclei squeezed, so to speak, to a pulp. During that early stage of evolution, matter must have been dissociated into its elementary components... . We call this primordial mixture ylem.

At this first point in the evolution of the present cycle, according to this first-rank physicist, there existed only the Unbecome, the Unborn, the Unformed. And this, according to astrophysicists, is the way it will end; the silent unity of the Unformed. The Tibetan Buddhists suggest that the uncluttered intellect can experience what astrophysics confirms. The Buddha Vairochana, the Dhyani Buddha of the Center, Manifester of Phenomena, is the highest path to enlightenment. As the source of all organic life, in him all things visible and invisible have their consummation and absorption. He is associated with the Central Realm of the Densely-Packed, i.e., the seed of all universal forces and things are densely packed together. This remarkable convergence of modern astrophysics and ancient lamaism demands no complicated explanation. The cosmological awareness - and awareness of every other natural process - is there in the cortex. You can confirm this preconceptual mystical knowledge by empirical observation and measurement, but it's all there inside your skull. Your neurons "know" because they are linked directly to the process, are part of it.] The mind in its conditioned state, that is to say, when limited to words and ego games, is continuously in thought-formation activity. The nervous system in a state of quiescence, alert, awake but not active is comparable to what Buddhists call the highest state of dhyana (deep meditation) when still united to a human body. The conscious recognition of the Clear Light induces an ecstatic condition of consciousness such as saints and mystics of the West have called illumination.

The first sign is the glimpsing of the "Clear Light of Reality," "the infallible mind of the pure mystic state." This is the awareness of energy transformations with no imposition of mental categories.

The duration of this state varies with the individual. It depends upon experience, security, trust, preparation and the surroundings. In those who have had even a little practical experience of the tranquil state of non-game awareness, and in those who have happy games, this state can last from thirty minutes to several hours.

In this state, realization of what mystics call the "Ultimate Truth" is possible, provided that sufficient preparation has been made by the person beforehand. Otherwise he cannot benefit now, and must wander on into lower and lower conditions of hallucinations, as determined by his past games, until he drops back to routine reality.

It is important to remember that the conscious-expansion process is the reverse of the birth process, birth being the beginning of game life and the ego-loss experience being a temporary ending of game life. But in both there is a passing from one state of consciousness into another. And just as an infant must wake up and learn from experience the nature of this world, so likewise a person at the moment of consciousness expansion must wake up in this new brilliant world and become familiar with its own peculiar conditions.

In those who are heavily dependent on their ego games, and who dread giving up their control, the illuminated state endures only so long as it would take to snap a finger. In some, it lasts as long as the time taken for eating a meal.

If the subject is prepared to diagnose the symptoms of ego loss, he needs no outside help at this point. Not only should the person about to give up his ego be able to diagnose the symptoms as they come, one by one, but he should also be able to recognize the Clear Light without being set face to face with it by another person. If the person fails to recognize and accept the onset of ego loss, he may complain of strange bodily symptoms. This shows that he has not reached a liberated state. Then the guide or friend should explain the symptoms as indicating the onset of ego loss.

Here is a list of commonly reported physical sensations:

1. Bodily pressure, which the Tibetans call earth-sinking-into-water;
2. Clammy coldness, followed by feverish heat, which the Tibetans call water-sinking-into-fire;
3. Body disintegrating or blown to atoms, called fire-sinking-into-air;
4. Pressure on head and ears, which Americans call rocket-launching-into-space;
5. Tingling in extremities;
6. Feelings of body melting or flowing as if wax;
7. Nausea;
8. Trembling or shaking, beginning in pelvic regions and spreading up torso.

These physical reactions should be recognized as signs heralding transcendence. Avoid treating them as symptoms of illness, accept them, merge with them, enjoy them.

Mild nausea occurs often with the ingestion of morning-glory seeds or peyote, rarely with mescaline and infrequently with LSD or psilocybin. If the subject experiences stomach messages, they should be hailed as a sign that consciousness is moving around in the body. The symptoms are mental; the mind controls the sensation, and the subject should merge with the sensation, experience it fully, enjoy it and, having enjoyed it, let consciousness flow on to the next phase. It is usually more natural to let consciousness stay in the body - the subject's attention can move from the stomach and concentrate on breathing, heart beat. If this does not free him from nausea, the guide should move the consciousness to external events - music, walking in the garden, etc.

The appearance of physical symptoms of ego-loss, recognized and understood, should result in peaceful attainment of illumination. If ecstatic acceptance does not occur (or when the period of peaceful silence seems to be ending), the relevant sections of the instructions can be spoken in a low tone of voice in the ear. It is often useful to repeat them distinctly, clearly impressing them upon the person so as to prevent his mind from wandering. Another method of guiding the experience with a minimum of activity is to have the instructions previously recorded in the subject's own voice and to flip the tape on at the appropriate moment. The reading will recall to the mind of the voyager the former preparation; it will cause the naked consciousness to be recognized as the "Clear Light of the Beginning;" it will remind the subject of his unity with this state of perfect enlightenment and help him to maintain it.

If, when undergoing ego-loss, one is familiar with this state, by virtue of previous experience and preparation, the Wheel of Rebirth (i.e., all game playing) is stopped, and liberation instantaneously is achieved. But such spiritual efficiency is so very rare, that the normal mental condition of the person is unequal to the supreme feat of holding on to the state in which the Clear Light shines; and there follows a progressive descent into lower and lower states of the Bardo existence, and then rebirth. The simile of a needle balanced and set rolling on a thread is used by the lamas to elucidate this condition. So long as the needle retains its balance, it remains on the thread. Eventually, however, the law of gravitation (the pull of the ego or external stimulation) affects it, and it falls. In the realm of the Clear Light, similarly, the mentality of a person in the ego-transcendent state momentarily enjoys a condition of balance, of perfect equilibrium, and of oneness. Unfamiliar with such a state, which is an ecstate state of non-ego, the consciousness of the average human being lacks the power to function in it. Karmic (i.e., game) propensities becloud the consciousness-principle with thoughts of personality, of individualized being, of dualism. Thus, losing equilibrium, consciousness falls away from the Clear Light. It is thought processes which prevent the realization of Nirvana (which is the "blowing out of the flame" of selfish game desire); and so the Wheel of Life continues to turn.

All or some of the appropriate passages in the instructions may be read to the voyager during the period of waiting for the drug to take effect, and when the first symptoms of ego-loss appear. When the voyager is clearly in a profound ego-transcendent ecstasy, the wise guide will remain silent.

Part II: The Secondary Clear Light Seen Immediately After Ego-Loss

The preceding section describes how the Clear Light may be recognized and liberation maintained. But if it becomes apparent that the Primary Clear Light has not been recognized, then it can certainly be assumed there is dawning what is called the phase of the Secondary Clear Light. The first flash of experience usually produces a state of ecstasy of the greatest intensity. Every cell in the body is sensed as involved in orgastic creativity.

It may be helpful to describe in more detail some of the phenomena which often accompany the moment of ego-loss. One of these might be called "wave energy flow." The individual becomes aware that he is part of and surrounded by a charged field of energy, which seems almost electrical. In order to maintain the ego-loss state as long as possible, the prepared person will relax and allow the forces to flow through him. There are two dangers to avoid: the attempt to control or to rationalize this energy flow. Either of these reactions is indicative of ego-activity and the First Bardo transcendence is lost.

The second phenomenon might be called "biological life-flow." Here the person becomes aware of physiological and biochemical processes; rhythmic pulsing activity within the body. Often this may be sensed as powerful motors or generators continuously throbbing and radiating energy. An endless flow of cellular forms and colors flashes by. Internal biological processes may also be heard with characteristic swooshing, crackling, and pounding noises. Again the person must resist the temptation to label or control these processes. At this point you are tuned in to areas of the nervous system which are inaccessible to routine perception. You cannot drag your ego into the molecular processes of life. These processes are a billion years older than the learned conceptual mind.

Another typical and most rewarding phase of the First Bardo involves ecstatic energy movement felt in the spine. The base of the backbone seems to be melting or seems on fire. If the person can maintain quiet concentration the energy will be sensed as flowing upwards. Tantric adepts devote decades of concentrated meditation to the release of these ecstatic energies which they call Kundalini, the Serpent Power. One allows the energies to travel upwards through several ganglionic centers (chakras) to the brain, where they are sensed as a burning sensation in the top of the cranium. These sensations are not unpleasant to the prepared person, but, on the contrary, are accompanied by the most intense feelings of joy and illumination. Ill-prepared subjects may interpret the experience in pathological terms and attempt to control it, usually with unpleasant results. [Professor R. C. Zaehner, who as an Oriental scholar and "expert" on mysticism should have know better, has published an account of how this prized experience can be lost and distorted into hypochondriacal complaint in the ill-educated.

... I had a curious sensation in my body which reminded me of what Mr. Custance describes as a "tingling at the base of the spine," which according to him, usually precedes a bout of mania. It was rather like that. In the Broad Walk this sensation occurred again and again until the climax of the experiment was reached ... I did not like it at all. (R. C. Zaehner: Mysticism, Sacred and Profane. Oxford Univ. Press, 1957, p. 214)

If the subjects fails to recognize the rushing flow of First Bardo phenomena, liberation from the ego is lost. The person finds himself slipping back into mental activities. At this point he should try to recall the instructions or be reminded of them, and a second contact with these processes can be made. The second stage is less intense. A ball set bouncing reaches its greatest height at the first bounce; the second bounce is lower, and each succeeding bounce is still lower until the ball comes to rest. The consciousness at the loss of the ego is similar to this. Its first spiritual bound, directly upon leaving the body-ego, is the highest; the next is lower. Then the force of karma, (i.e., past game-playing), takes over and different forms of external reality are experienced. Finally, the force of karma having spent itself, consciousness returns to "normal." Routines are taken up again and thus rebirth occurs.

The first ecstasy usually ends with a momentary flashback to the ego condition. This return can be happy or sad, loving or suspicious, fearful or courageous, depending on the personality, the preparation, and the setting.

This flashback to the ego-game is accompanied by a concern with identity. "Who am I now? Am I dead or not dead? What is happening?" You cannot determine. You see the surroundings and your companions as you had been used to seeing them before. There is a penetrating sensitivity. But you are on a different level. Your ego grasp is not quite as sure as it was.

The karmic hallucinations and visions have not yet started. Neither the frightening apparitions nor the heavenly visions have begun. This is a most sensitive and pregnant period. The remainder of the experience can be pushed one way or another depending upon preparation and emotional climate.

If you are experienced in consciousness alteration, or if you are a naturally introverted person, remember the situation and the schedule. Stay calm and let the experience take you where it will. You will probably re-experience the ecstasy of illumination once again; or you may drift into aesthetic or philosophic or interpersonal enlightenments. Don't hold on: let the stream carry you along.

The experienced person is usually beyond dependence on setting. He can turn off external pressure and return to illumination. An extroverted person, dependent upon social games and outside situations may, however, become pleasantly distracted (colors, sounds, people). If you anticipate extroverted distraction and if you want to maintain a non-game state of ecstasy, then remember the following suggestions: do not be distracted; try to concentrate on an ideal contemplative personage, e.g., Buddha, Christ, Socrates, Ramakrishna, Einstein, Herman Hesse or Lao Tse: follow his model as if he were a being with a physical body waiting for you. Join him.

If this is not successful, don't fret or think about it. Perhaps you don't have a mystical or transcendental ideal. That means your conceptual limits are within external games. Now that you know what the mystic experience is, you can prepare for it next time. You have lost the content-free flow and should now be ready to slip into exciting confrontation with external reality. In the Second Bardo you can reach and deeply experience game revelations.

We have just anticipated the reactions of the naturally mystical introvert, the experienced person, and the extrovert. Now let's turn to the novitiate who shows confusion at this early stage of the sequence. The best procedure is to make a reassuring sign and do nothing. He will have read this manual and will have some guidepost. Leave him alone and he will probably dive into his panic and master it. If he indicates that he wishes guidance, repeat the instructions. Tell him what is happening. Remind him of his phase in the process. Urge him quietly to release his ego struggle and drift back into contact with the Clear Light.

Preparation and guidance of this sort will allow many to reach the illuminated state who would not be expected to recognize it.

At this point, it is necessary to inject a word of benign warning. Reading this manual is extremely useful, but no words can communicate experience. You are going to be surprised, startled and delighted. A person may have heard a detailed description of the art of swimming and yet never had the chance to swim. Suddenly diving into the water, he finds himself unable to swim. So with those who have tried to learn the theory of how to experience ego-loss, and have never applied it. They cannot maintain unbroken continuity of consciousness, they grow bewildered at the changed condition; they fail to maintain the mystical ecstasy; they fail to take advantage of the opportunity unless upheld and directed by a guide. Even with all that a guide can do, they ordinarily, because of bad karma (heavy ego games) fail to recognize the liberation. But this is no cause for worry. At the worst, they just slip back to shore. No one has drowned, and most of those who have taken the voyage have been eager to try again.

Even those who have familiarized themselves with the road maps and who previously have had illumination, may find themselves in settings where heavy game behavior on the part of others forces them into contact with external reality. If this happens, recall the instructions. The person who masters this principle can block out the external. The one who has mastered control of consciousness is independent of setting.

Again there are those, who although previously successful, may have brought ego games into the session with them. They may want to provide someone else with a particular type of experience. They may be promoting some self goal. They may be nurturing negative or competitive or seductive feelings towards someone in the session. If this happens, recall the instructions. Remember the unity of all beings. One to me is shame and fame. One to me is loss or gain. Jettison your ego program and float back to the radiant bliss of at-one-ness.

If you reach the Clear Light immediately and maintain it, that is best. But if not, if you have slipped down to reality concerns, by remembering these instructions you should be able to regain what the Tibetans call the Secondary Clear Light.

While on this secondary level, an interesting dialogue occurs between pure transcendence and the awareness that this ecstatic vision is happening to oneself. The first radiance knows no self, no concepts. The secondary experience involves a certain state of conceptual lucidity. The knowing self hovers within that transcendent terrain from which it is usually barred. If the instructions are remembered, external reality will not intrude. But the flashing in and out between pure ego-less unity, and lucid, non-game selfhood, produces an intellectual ecstasy and understanding that defies description. Previous philosophic reading will suddenly take on living meaning.

Thus in this secondary stage of the First Bardo, there is possible both the mystic non-self and the mystic self experience.

After you have experienced these two states, you may wish to pursue this distinction intellectually. We are confronted here with one of the oldest debates in Eastern philosophy. Is it better to be part of the sugar or to taste the sugar? Theological controversies and their dualities are far removed from experience. Thanks to the experimental mysticism made possible by consciousness-expanding drugs, you may have been lucky enough to have experienced the flashing back and forth between the two states. You may be lucky enough to know what the academic monks could only think about.

Here ends the First Bardo, The Period of Ego-loss or Non-Game Ecstasy

Second Bardo: The Period Of Hallucinations (Chonyid Bardo)

Introduction

If the Primary Clear Light is not recognized, there remains the possibility of maintaining the Secondary Clear Light. If that is lost, then comes the Chonyid Bardo, the period of karmic illusions or intense hallucinatory mixtures of game reality. It is very important that the instructions be remembered - they can have great influence and effect.

During this period, the flow of consciousness, microscopically clear and intense, is interrupted by fleeting attempts to rationalize and interpret. But the normal game-playing ego is not functioning effectively. There exist, therefore, unlimited possibilities for, on the one hand, delightful sensuous, intellectual and emotional novelties if one floats with the current; and, on the other hand, fearful ambuscades of confusion and terror if one tries to impose his will on the experience.

The purpose of this part of the manual is to prepare the person for the choice points which arise during this stage. Strange sounds, weird sights and disturbed visions may occur. These can awe, frighten and terrify unless one is prepared.

The experienced person will be able to maintain the recognition that all perceptions come from within and will be able to sit quietly, controlling his expanded awareness like a phantasmagoric multi-dimensional television set: the most acute and sensitive hallucinations - visual, auditory, touch, smell, physical and bodily; the most exquisite reactions, compassionate insight into the self, the world. The key is inaction: passive integration with all that occurs around you. If you try to impose your will, use your mind, rationalize, seek explanations, you will get caught in hallucinatory whirlpools. The motto: peace, acceptance. It is all an ever-changing panorama. You are temporarily removed from the world of game. Enjoy it.

The inexperienced and those to who ego control is important may find this passivity impossible. If you cannot remain inactive and subdue your will, then the one certain activity which can reduce panic and pull you out of hallucinatory mind-games is physical contact with another person. Go to the guide or to another participant and put your head on his lap or chest; put your face next to his and concentrate on the movement and sound of his inspiration. Breathe deeply and feel the air rush in and the sighing release. This is the oldest form of living communication; the brotherhood of breath. The guide's hand on your forehead may add to the relaxation.

Contact with another participant may be misunderstood and provoke sexual hallucinations. For this reason, helping contact should be made explicit by prearrangement. Unprepared participants may impose sexual fears or fantasies on the contact. Turn them off; they are karmic illusory productions.

The tender, gentle, supportive huddling together of participants is a natural development during the second phase. Do not try to rationalize this contact. Human beings and, for that matter, most all mobile terrestrial creatures have been huddling together during long, dark confused nights for several hundred thousand years.

Breathe in and breathe out with you companions. We are all one! That's what your breath is telling you.

Explanation of the Second Bardo

The underlying problem of the Second Bardo is that any and every shape - human, divine, diabolical, heroic, evil, animal, thing - which the human brain conjures up or the past life recalls, can present itself to consciousness: shapes and forms and sounds whirling by endlessly.

The underlying solution - repeated again and again - is to recognize that your brain is producing the visions. They do not exist. Nothing exists except as your consciousness gives it life.

You are standing on the threshold of recognizing the truth: there is no reality behind any of the phenomena of the ego-loss state, save the illusions stored up in your own mind either as accretions from game (Sangsaric) experience or as gifts from organic physical nature and its billion-year old past history. Recognition of this truth gives liberation.

There is, of course, no way of classifying the infinite permutations and combinations of visionary elements. The cortex contains file-cards for billions of images from the history of the person, of the race, and of living forms. Any of these, at the rate of a hundred million per second (according to neuro-physiologists), can flood into awareness. Bobbing around in this brilliant, symphonic sea of imagery is the remnant of the conceptual mind. On the endless watery turbulence of the Pacific Ocean bobs a tiny open mouth shouting (between saline mouthfuls), "Order! System! Explain all this!"

One cannot predict what visions will occur, nor their sequence. One can only urge the participants to shut the mouth, breathe through the nose, and turn off the fidgety, rationalizing mind. But only the experienced person of mystical bent can do this (and thus remain in serene enlightenment). The unprepared person will be confused or, worse, panicky: the intellectual struggle to control the ocean.

In order to guide the person, to help him organize his visions into explicable units, the Chonyid Bardo was written. There are two sections: (1) Seven Peaceful Deities with their symmetrically opposed ego traps. (2) Eight Wrathful Deities who can be joyfully accepted as visionary productions, or fled from in terror.

Each of the Seven Peaceful Deities (bisexual Father-Mother figures) are accompanied by consorts, attendants, lesser deities, saints, angels, heroes. Each of the Wrathful Deities is similarly accompanied. Lights, symbolic objects, beautiful, horrid, threatening, seething, are likewise seen.

If read literally, The Tibetan Book of the Dead would have you expect the "Master of All Visible Shapes" (or his opposite, the fondness for stupidity) on the first day; the "Immovable Deity of Happiness" and his consort, attendants and opposite on the second, etc. The manual should, of course, not be used rigidly, exoterically, but should be taken in its esoteric, allegorical form.

Read from this perspective, we see that the lamas have listed or named a thousand images which can boil up in the ever-changing jeweled mosaic of the retina (that multi-layered swamp of billions of rods and cones, infiltrated, like a Persian rug or a Mayan carving, with countless multi- colored capillaries). By preparatory reading of the manual and by its repetition during the experience, the novice is led via suggestion to recognize this fantastic retinal kaleidoscope.

Most important, he is told that they come from within. All deities and demons, all heavens and hells are internal.

The student with a particular interest in Tibetan or Tantric Buddhism should steep himself in the text of the Chonyid Bardo. He should obtain colored plates of the fourteen dramas of the Bardo, and he should arrange to have the guide lead him through the prescribed sequence during the drug session. This will provide an unforgettable series of liberations and will permit the devotee to emerge from the experience "reincarnated" in the lamaist tradition.

The aim of this manual is to make available the general outline of the Tibetan Book and to translate it into psychedelic English. For this reason we shall not present the detailed sequence of lamaist hallucinations but, rather, list some apparitions commonly reported by Westerners.

Following the Tibetan Thodo, we have classified Second Bardo visions into seven types:

1. The Source or Creator Vision
2. The Internal Flow of Archetypal Processes
3. The Fire-Flow of Internal Unity
4. The Wave-Vibration Structure of External Forms
5. The Vibratory Waves of External Unity
6. "The Retinal Circus"
7. "The Magic Theatre" [We owe the phrase "retinal circus" to Henri Michaux (Miserable Miracle), and the term "magic theatre" to Hermann Hesse (Steppenwolf).

Visions 2 and 3 involve closed eyes and no contact with external stimuli. In Vision 2 the internal imagery is primarily conceptual. The experience can range from revelation and insight to confusion and chaos, but the cognitive, intellectual meaning is paramount. In Vision 3 the internal imagery is primarily emotional. The experience can range from love and ecstatic unity to fear, distrust and isolation.

Visions 4 and 5 involve open eyes and rapt attention to external stimuli, such as sounds, lights, touch, etc. In Vision 4 the external imagery is primarily conceptual and in Vision 5 emotional factors predominate.

The sevenfold table just defined bears some similarity to the mandalic schema of the Peaceful Deities listed for the Second Bardo in The Tibetan Book of the Dead.

The Peaceful Visions

Vision 1: The Source
(Eyes closed, external stimuli ignored)

[The first Peaceful Deity listed by the Bardo Thodol is the Bhagavan Vairochana who occupies the center of the mandala of the five Dhyani-Buddhas. His attributes of source-power have been translated into those of the monotheistic creator of Western religions.]

The White Light, or First Bardo energy, may be interpreted as God the Creator. The Spreader of the Seed. The Power which makes all shapes visible. Seed of all that is. Sovereign Power. The All-Powerful. The Central Sun. The One Truth. The Source of all Organic Life. The Divine Mother. The Female Creative Principle. Mother of the Space of Heaven. Radiant Father- Mother. Magnificent revelations, both spiritual and philosophic, can occur at this point making the highest union of experience and intellect. But, because of bad karma (usually religious beliefs of a monotheistic or punitive nature), the glorious light of the seed wisdom it can produce awe and terror. The person will wish to flee and will beget a fondness for the dull white light symbolizing stupidity.

Persons from a Judaeo-Christian background conceive of an enormous gulf between divinity (which is "up there") and the self ("down here"). Christian mystics' claims to unity with divine radiance has always posed problems for theologians who are committed to the cosmological subject-object distinction. Most Westerners, therefore, find it difficult to attain unity with the source-light.

If the guide ascertains that the voyager is struggling with thoughts or feelings about the creative source energy, he can read the appropriate instructions. (See Instructions For Vision 1: The Source)

Vision 2: The Internal Flow of Archetypal Processes
(Eyes closed, external stimuli ignored; intellectual aspects)

If the undifferentiated light of the First Bardo or of the Source Energy is lost, luminous waves of differentiated forms can flood through the consciousness. The person's mind begins to identify these figures, that is, to label them and experience revelations about the life process. [Lama Govinda tells us that Amoghasiddhi represents "... the mysterious activity of spiritual forces, which work removed from the senses, invisible and imperceptible, with the aim of guiding the individual (or, more properly: all living beings) towards the maturity of knowledge and liberation. The yellow light of an (inner) sun invisible to human eyes ... (in which the unfathomable space of the universe seems to open itself) for the serene mystic green of Amoghasiddhi... . On the elementary plane this all- pervading power corresponds to the element of air - the principle of movement and extension, of life and breath (prana)." Lama Govinda: Foundations of Tibetan Mysticism. Lodon: E. P. Dutton & Co., Inc., 1959, p.120.

The fifth day of the Baro Thodol confronts the deceased with the Bhagavan Buddha Amoghasiddhi, Almighty Conqueror, from the green Norther realm of Successful Performance of Best Actions, attended by a Divine Mother, and two Bodhisattvas representing the mental functions of "equilibrium, immutability, and almighty power" and "clearer of obscurations."]

Specifically, the subject is caught up in an endless flow of colored forms, microbiological shapes, cellular acrobatics, capillary whirling. The cortex is turned in on molecular processes which are completely new and strange: a Niagara of abstract designs; the life-stream flowing, flowing.

These visions might perhaps be described as pure sensations of cellular and sub-cellular processes. It is uncertain whether they involve the retina and/or the visual cortex, or whether they are flashes of direct, molecular sensation in other areas of the central nervous system. They are subjectively described as internal visions.

Another class of internal process images involves sound. Again we do not know whether these sensations originate in the auditory apparatus and/or in the auditory cortex, or whether they are flashes of direct, molecular sensations in other areas. They are subjectively described as internal sounds: clicking, thudding, clashing, soughing, ringing, tapping, moaning, shrill whistles. [The Tibetan Book includes a brilliant discussion of internal process noises. "... innumerable (other) kinds of musical instruments, filling (with music) the whole world-systems and causing them to vibrate, to quake and tremble with sounds so mighty as to daze one's brain... ."

"Tibetan lamas, in chanting their rituals, employ seven (or eight) sorts of musical instruments: big drums, cymbals (commonly brass), conch shells, bells (like the handbells used in the Christian Mass Service), timbrels, small clarionets (sounding like Highland bagpipes), big trumpets, and human thighbone trumpets. Although the combined sounds of these instruments are far from being melodious, the lamas maintain that they psychically produce in the devotee an attitude of deep veneration and faith, because they are the counterparts of the natural sounds which one's own body is heard producing when the fingers are put in the ears to shut out external sounds. Stopping the ears thus, there are heard a thudding sound, like that of a big drum being beaten; a clashing sound, as of cymbals; a soughing sound, as of a wind moving through a forest - as when a conch-shell is bone; a ringing as of bells; a sharp tapping sound, as when a timbrel is used; a moaning sound, like that of a clarionet; a bass moaning sound, as if made with a big trumpet; and a shriller sound, as of a thigh-bone trumpet."

"Not only is this interesting as a theory of Tibetan sacred music, but it gives the clue to the esoteric interpretation of the symbolical natural sounds of Truth (referred to in the second paragraph following, and elsewhere in our text), which are said to be, or to proceed from, the intellectual faculties within the human mentality." - (Evans-Wentz, p. 128)] These noises, like the visions, are direct sensations unencumbered by mental concepts. Raw, molecular, dancing units of energy.

The minds sweeps in and out of this evolutionary stream, creating cosmological revelations. Dozens of mythical and Darwinian insights flash into awareness. The person is allowed to glance back down the flow of time and to perceive how the life energy continually manifests itself in forms, transient, always changing, reforming. Microscopic forms merge with primal creative myths. The mirror of consciousness is held up to the life stream.

As long as the person floats with the current, he is exposed to a billion-year lesson in cosmology. But the drag of the mind is always present. The tendency to impose arbitrary, isolating order on the organic process.

Sometimes the voyager feels he should report back his vision. He converts the life flow into a cosmic ink-blot test - attempts to label each form. "Now I see a peacock's tail. Now Muslim knights in colored armor. Oh, now a waterfall of jewels. Now, Chinese music. Now, gem-like serpents, etc." Verbalizations of this sort dull the light, stop the flow and should not be encouraged.

Another trap is that of imposing a sexual interpretation. The dancing, playful flow of life is, in the most reverant sense, sexual. Forms merging, spinning together, reproducing. Eros in its countless manifestations. The Tibetans refer to the female Bodhisattvas Pushpema, personification of blossoms, and Lasema, the "Belle", depicted holding a mirror in a coquettish attitude. Keep the pure, spontaneous awareness of the Mirror-like Wisdom. Laugh joyously at the tricks of the life process, forever decking out forms in seductive, enticing patterns to keep the dance going. If the voyager interprets the visions of Eros in terms of his personal sexual game model, and attempts to think or plan - "what should I do? what role should I play?" - he is likely to slip down into the Third Bardo. Sexual plots dominate his awareness, the flow fades, the mirror tarnishes, and he is rudely reborn as a confused, thinking being.

Still another impasse is the imposition of physical symptom games upon the biological flow. The new somatic sensations may be interpreted as symptoms. If it is new, it must be bad. Any organ of the body may be selected as the focus of the "illness." People whose primary expectation when taking a psychedelic substance is medical, are particularly likely to fall into this trap. Medical doctors are, in fact, extremely prone and can imagine colorful diseases and fatal attacks.

In the case of the most widely-used psychedelics (LSD, psilocybin, etc.), it is safe to say that such bodily effects are virtually never the direct effect of the drug. The drug acts only on the brain and activates central neural patterns. All physical symptoms are created by the mind. Bodily sickness is a sign that the ego is fighting to maintain or regain its hold over an outpouring of feeling, over a dissolution of emotional boundaries.

If the person complains of physical symptoms such as nausea or pain, the guide should read him the Instructions For Physical Symptoms.

The negative, wrathful counterpart to this vision occurs if the voyager reacts with fear to the powerful flow of life forms. Such a reaction is attributable to the cumulated result of game playing (karma) dominated by anger or stupidity. A nightmarish hell-world may ensue. The visual forms appear like a confusing chaos of cheap, ugly dime-store objects, brassy, vulgar and useless. The person may become terrified at the prospect of being engulfed by them. The awesome sounds may be heard as hideous, clashing, oppressive, grating noises. The person will attempt to escape from these perceptions into restless external activity (talking, moving around, etc.) or into conceptual, analytic, mental activity.

The experience is the same, the intellectual interpretation is different. Instead of revelation, there is confusion; instead of calm joy, there is fear. The guide, recognizing the voyager to be in such a state, can help him get free, by reading the Instructions for Vision 2.

Vision 3: The Fire-Flow of Internal Unity
(Eyes closed, external stimuli ignored, emotional aspects)

The First Bardo instructions should keep you face-to-face with the void-ecstasy. Yet there are classes of men who, having carried over karmic conflict about feeling-inhibition, prove unable to hold the pure experience beyond all feelings, and slip into emotionally toned visions. The undifferentiated energy of the First Bardo is woven into visionary games in the form of intense feelings. Exquisite, intense, pulsating sensations of unity and love will be felt; the negative counterpart is feelings of attachment, greed, isolation and bodily concerns.

It comes about this way: the pure flow of energy loses its white void quality and becomes sensed as intense feelings. An emotional game is imposed. Incredible new physical sensations pulse through the body. The glow of life is felt flooding along veins. One merges into a unitive ocean of orgastic, fluid electricity, [The Peaceful Deity of the Bardo Thodol personifying this vision is the Buddha Amitabbha, the all-discriminating wisdom and feeling, boundless light, representing life eternal. Lama Govinda writes that "The deep red light of discriminating inner vision shines forth from his heart ... fire corresponds to him and thus, according to the ancient traditional symbolism, the eye and the function of seeing." (Govinda, op. cit., p. 120.) With the Bhagavan Amitabbha comes the Bodhisattva Chenrazee, embodiment of mercy or compassion, the great pitier ever on the lookout to discover distress and to succour the troubled. He is joined by the Bodhisattva "Glorious Gentle-voiced One," and the female incarnates "song" and "light."] the endless flow of shared-life, of love.

Visions related to the circulatory system are common. The subject tumbles down through his own arterial network. The motor of the heart reverberates as one with the pulsing of all life. The heart then breaks, and red fire bleeds out to merge with all living beings. All living organisms are throbbing together. One is joyfully aware of the two-billion-year-old electric sexual dance; one is at last divested of robot clothes and limbs and undulates in the endless chain of living forms.

Dominating this ecstatic state is the feeling of intense love. You are a joyful part of all life. The memory of former delusions of self-hood and differentiation invokes exultant laughter.

All the harsh, dry, brittle angularity of game life is melted. You drift off - soft, rounded, moist, warm. Merged with all life. You may feel yourself floating out and down into a warm sea. Your individuality and autonomy of movement are moistly disappearing. Your control is surrendered to the total organism. Blissful passivity.

Ecstatic, orgiastic, undulating unity. All worries and concerns wash away. All is gained as everything is given up. There is organic revelation. Every cell in your body is singing its song of freedom - the entire biological universe is in harmony, liberated from the censorship and control of you and your restricted ambitions.

But wait! You, You, are disappearing into the unity. You are being swallowed up by the ecstatic undulation. Your ego, that one tiny remaining strand of self, screams STOP! You are terrified by the pull of the glorious, dazzling, transparent, radiant red light. You wrench yourself out of the life-flow, drawn by your intense attachment to your old desires. There is a terrible rending as your roots tear out of the life matrix - a ripping of your fibres and veins away from the greater body to which you were attached. And when you have cut yourself off from the fire-flow of life the throbbing stops, the ecstasy ceases, your limbs harden and stiffen into angular forms, your plastic doll body has regained its orientation. There you sit, isolated from the stream of life, impotent master of your desires and appetites, miserable.

While you are floating down the evolutionary river, there comes a sense of limitless self-less power. The delight of flowing cosmic belongingness. The astounding discovery that consciousness can tune in to an infinite number of organic levels. There are billions of cellular processes in your body, each with its universe of experience - an endless variety of ecstasies. The simple joys and pains and burdens of your ego represent one set of experiences - a repetitious, dusty set. As you slip into the fire-flow of biological energy, series after series of experiential sets flash by. You are no longer encapsulated in the structure of ego and tribe.

But through panic and a desire to latch on to the familiar, you shut off the flow, open your eyes; then the flowingness is lost. The potentiality to move from one level of consciousness to another is gone. Your fear and desire to control have driven you to settle for one static site of consciousness. To use the Eastern or genetic metaphor, you have frozen the dance of energy and committed yourself to one incarnation, and you have done it out of fear.

When this happens, there are several steps which can take you back to the biological flow (and from there to the First Bardo). First, close your eyes. Lie on you stomach and let you body sink through the floor, merge with the surroundings. Feel the hard, square edges of your body soften and start to move in the bloodstream. Let the rhythm of breathing become tide flow. Bodily contact is probably the most effective method of softening hardened surfaces. No movement. No body games. Close physical contact with another invariably brings about the unity of fire-flow. Your blood begins to flow into the other's body. His breathing pours into your lungs. You both drift down the capillary river.

Another form of life process images is the flow of auditory sensations. The endless series of abstract sounds (described in the preceding vision) bounce through awareness. The emotional reaction to these can be neutral or can involve intense feelings of unity, or of annoyed fear.

The positive reaction occurs when the subject merges with the sound flow. The thudding drum of the heart is sensed as the basic anthem of humanity. The whooshing sough of the breath as the rushing river of all life. Overwhelming feelings of love, gratitude and oneness funnel into the moment of sound, into each note of the biological concerto.

But, as always, the voyager may intrude his personality with its wants and opinions. He may not "like" the noise. His judgmental ego may be aesthetically offended by the sounds of life. The heart thud is, after all, monotonous; the natural music of the inner ear, with its clicks and hums and whistles, lacks the romantic symmetries of Beethoven. The terrible separation of "me" from my body occurs. Horrible. Out of my control. Turn it off.

The trained guide can usually sense when ego-attachment threatens to pull the person out of the unitive flow. At this time he can guide the voyager by reading the Instructions for Vision 3.

Vision 4: The Wave-Vibration Structure of External Forms
(Eyes open or rapt involvement with external stimuli; intellectual aspects)

The pure, content-free light of the First Bardo probably involves basic electrical wave energy. This is nameless, indescribable, because it is far beyond any concepts which we now possess. Some future atomic physicist may be able to classify this energy. Perhaps it will always be ineffable for a nervous system such as that of homo sapiens. Can an organic system "comprehend" the vastly more efficient inorganic? At any event, most persons, even the most illuminated, find it impossible to maintain experiential contact with this void-light and slip back to imposing mental structures, hallucinatory and revelatory, upon the flow.
Thus we are brought to another frequent vision which involves intense, rapt, unitive awareness of external stimuli. If the eyes are open, this super-reality effect can be visual. The penetrating impact of other stimuli can also set off revelatory imagery.

It comes about this way. The subject's awareness is suddenly invaded by an outside stimulus. His attention is captured, but his old conceptual mind is not functioning. But other sensitivities are engaged. He experiences direct sensation. The raw "is-ness." He sees, not objects, but patterns of light waves. He hears, not "music" or "meaningful" sound, but acoustic waves. He is struck with the sudden revelation that all sensation and perception are based on wave vibrations. That the world around him which heretofore had an illusory solidity, is nothing more than a play of physical waves. That he is involved in a cosmic television show which has no more substantiality than the images on his TV picture tube. [The Peaceful Deity of the Thodol personifying this vision is Akshobhya. According to Lama Govinda, "In the light of the Mirror-like Wisdom ... things are freed from their "thingness," their isolation, without being deprived of their form; they are divested of their materiality, without being dissolved, because the creative principle of the mind, which is at the bottom of all form and materiality, is recognized as the active side of the universal Store Consciousness (alaya-vijnana), on the surface of which forms arise and pass away, like the waves on the surface of the ocean... ." (Govinda, op. cit., p. 119.)

The atomic structure of matter is, of course, known to us intellectually, but never experienced by the adult except in states of intense altered consciousness. Learning from a physics textbook about the wave structure of matter is one thing. Experiencing it - being in it - with the old, familiar, gross, hallucinatory comfort of "solid" things gone and unavailable, is quite another matter.

If these super-real visions involve wave phenomena, then the external world takes on a radiance and a revelation that is staggeringly clear. The experienced insight that the world of phenomena exists in the form of waves, electronic images, can produce a sense of illuminated power. Everything is experienced as consciousness.

These exultant radiations should be recognized as productions of your own internal processes. You should not attempt to control or conceptualize. This can come later. There is the danger of hallucinatory freezing. The subject rushes back (sometimes literally) to the three-dimensional reality, convinced of the fixed "truth" of one experienced revelation. Many misguided mystics and many persons called insane have fallen into this ambuscade. This is like making a still photograph of a television pattern and shouting that one has finally seized the truth. All is ecstatic electric Maya, the two- billion-year dance of waves. No one part of it is more real than another. Everything at all moments is shimmering with all the meaning.

So far we have considered the positive radiance of clarity; but there are fearful negative aspects of the fourth vision. When the subject senses that his "world" is fragmenting into waves, he may become terrified. "He," "me," "I" are dissolving! The world around me is supposed to sit, static and dead, quietly awaiting my manipulation. But these passive things have changed into a shimmering dance of living energy! The Maya nature of phenomena creates panic. Where is the solid base? Every thing, every concept, every form upon which one rests one's mind collapses into electrical vibrations lacking solidity.

The face of the guide or of one's beloved friend becomes a dancing mosaic of impulses on one's cortex. "My consciousness" has created everything of which I am conscious. I have kinescoped my world, my loved ones, myself. All are just shimmering energy patterns. Instead of clarity and exultant power, there is confusion. The subject staggers around, grasping at electron-patterns, striving to freeze them back into the familiar robot forms.

All solidity is gone. All phenomena are paper images pasted on the glass screen of consciousness. For the unprepared, or for the person whose karmic residue stresses control, the discovery of the wave-nature of all structure, the Maya revelation, is a disastrous web of uncertainty.

We have discussed only the visual aspects of the fourth vision. Auditory phenomena are of equal importance. Here the solid, labelled nature of auditory patterns is lost, and the mechanical impact of sound hitting the eardrum is registered. In some cases, sound becomes converted into pure sensation, and synesthesia (mixture of sense modalities) occurs. Sounds are experienced as colors. External sensations hitting the cortex are recorded as molecular events, ineffable.

The most dramatic auditory visions occur with music. Just as any object radiates a pattern of electrons and can become the essence of all energy, so can any note of music be sensed as naked energy trembling in space, timeless. The movement of notes, like the shuttling of oscillograph beams. Each capturing all energy, the electric core of the universe. Nothing existing except the needle-clear resonance on the tympanic membrane. Unforgettable revelations about the nature of reality occur at these moments.

But the hellish interpretation is also possible. As the learned structure of sound collapses, the direct impact of waves can be sensed as noise. For one who is compelled to institute order, his order, on the world around him, it is at least annoying and often disturbing to have the raw tattoo of sound resonating in consciousness.

Noise! What an irreverent concept. Is not everything noise; all sensation the divine pattern of wave energy, meaningless only to those who insist on imposing their own meaning?

Preparation is the key to a serene passage through this visionary territory. The subject who has studied this manual will be able, when face to face with the phenomenon, to recognize and flow with it.

The sensitive guide will be ready to pick up, on any cue, that the subject is wandering in the fourth vision. If the voyager's eyes are open (indicating visual reactions), he can read the Instructions for Vision 4.

If the guide senses that the voyager is experiencing the fragmentation of external sound into wave vibrations, he can amend the instructions appropriately (changing the visual references to auditory).

Vision 5: The Vibratory Waves of External Unity
(Eyes open, or rapt involvement with external stimuli; emotional aspects)

As the learned perceptions disappear and the structure of the external world disintegrates into direct wave phenomena, the aim is to maintain a pure, content-free awareness (First Bardo). Despite the preparations, one is likely to be led backwards by one's own mental inclinations into two hallucinatory or revelatory interpretations of reality. One reaction leads to the intellectual clarity or frightened confusion of the fourth vision (just described). Another interpretation is the emotional reaction to the fragmentation of differentiated forms. One can be engulfed in ecstatic unity, or one can slip into isolated egotism. The Bardo Thodol calls the former the "Wisdom of Equality" and the latter the "quagmire of worldly existence accruing from violent egotism." [The Peaceful Deity of the fifth vision comes in the form of the Bhagavan Ratnasambhava, born of a jewel. He is embraced by the Divine Mother, She of the Buddha Eyes, and accompanied by the Bodhisattvas, womb of the sky, All-good, and those holding incense and rosary. "On the elementary plane Ratnasambhava corresponds to the earth, which carries and nourishes all beings with the equanimity and patience of a mother, in whose eyes all beings, borne by her, are equal." (Govinda, op. cit., p. 119.)] In the state of radiant unity, one senses that there is only one network of energy in the universe and that all things and all sentient beings are momentary manifestations of the single pattern. When egotistic interpretations are imposed on the fifth vision, the "plastic doll" phenomena are experienced. Differentiated forms are seen as inorganic, dull, mass-produced, shabby, plastic, and all persons (including self) are seen as lifeless mannequins isolated from the vibrant dance of energy, which has been lost.

The experiential data of this vision are similar to that of the fourth vision. All artifactual learned structure collapses back to energy vibrations. The awareness is dominated not by revelatory clarity but by shimmering unity. The subject is entranced by the silent, whirling play of forces. Exquisite forms dance by him, all surrounding objects radiate energy, brilliant emanations. His own body is seen as a play of forces. If he looks in a mirror, he sees a shining mosaic of particles. The sense of his own wave structure becomes stronger. A feeling of melting, floating off. The body is no longer a separate unit but a cluster of vibrations sending and receiving energy - a phase of the dance of energy which has been going on for millennia.

A sense of profound one-ness, a feeling of the unity of all energy. Superficial differences of role, cast, status, sex, species, form, power, size, beauty, even the distinctions between inorganic and living energy, disappear before the ecstatic union of all in one. All gestures, words, acts and events are equivalent in value - all are manifestations of the one consciousness which pervades everything. "You," "I" and "he" are gone, "my" thoughts are "ours," "your" feelings are "mine." Communication is unnecessary, since complete communion exists. A person can sense another's feeling and mood directly, as if they were his own. By a glance, whole lifetimes and words can be transmitted. If all are at peace, the vibrations are "in phase." If there is discord, "out of phase" vibrations will be set up which will be felt like discordant music. Bodies melt into waves. Objects in the environment - lights, tree, plants, flowers - seem to open and welcome you: they are part of you. You are both simply different pulses of the same vibrations. A pure feeling of ecstatic harmony with all beings is the keynote of this vision.

But as before, terrors can occur. Unity requires ecstatic self-sacrifice. Loss of ego brings fright to the unprepared. The fragmentation of form into waves can bring the most terrible fear known to man: the ultimate epistemological revelation.

The fact of the matter is that all apparent forms of matter and body are momentary clusters of energy. We are little more than flickers on a multidimensional television screen. This realization directly experienced can be delightful. You suddenly wake up from the delusion of separate form and hook up to the cosmic dance. Consciousness slides along the wave matrices, silently at the speed of light.

The terror comes with the discovery of transience. Nothing is fixed, no form solid. Everything you can experience is "nothing but" electrical waves. You feel ultimately tricked. A victim of the great television producer. Distrust. The people around you are lifeless television robots. The world around you is a facade, a stage set. You are a helpless marionette, a plastic doll in a plastic world.

If others attempt to help, they are seen as wooden, waxen, feelingless, cold, grotesque, maniacal, space-fiction monsters. You are unable to feel. "I am dead. I will never live and feel again." In wild panic you may attempt to force feeling back - by action, by shouting. You will then enter the Third Bardo stage and be reborn in an unpleasant way.

The best method to escape from fifth vision terrors is to remember this manual, relax, and swing with the wave dance. Or to communicate to the guide that you are in a plastic doll phase, and he will guide you back.

Another solution is to move to the internal biological flow. Follow the instructions given in the third vision: close your eyes, lie prone, seek bodily contact, float down into your bodily stream. In so doing, you are recapitulating the evolutionary sequence. For billions of years, inorganic energy danced the cosmic round before the biological rhythm began. Don't rush it.

If the guide senses that the person is experiencing plastic doll visions or is afraid of the uncontrollability of his own feeling, he should read to him the Instructions for Vision 5.

Vision 6: "The Retinal Circus"

Each of the Second Bardo visions thus far described was one aspect of the "experiencing of reality." The inner fire or outer waves, apprehended intellectually or emotionally - each vision with its correspondent traps. Each of the "Peaceful Deities" appears with its attendant "Wrathful Deities." To maintain any of these visions for any length of time requires a certain degree of concentration or "one-pointedness" of mind, as well as the ability to recognize them and not to be afraid. Thus, for most persons, the experience may pass through one or more of these phases without the voyager being able to hold them or stay with them. He may open and close his eyes, he may become alternately absorbed in internal sensations and external forms. The experience may be chaotic, beautiful, thrilling, incomprehensible, magical, ever-changing. [In the Bardo Thodol, on the sixth day appear the radiant lights of the combined Five Wisdoms of the Dhyani- Buddhas, the protective deities (gatekeepers of the mandala) and the Buddhas of the Six Realms of game-existence. According to Lama Govinda: "The Inner Way of Vajra-Sattva, consists in the combination of the rays of the Wisdoms of the four Dhyani-Buddhas and their absorption within one's own heart - in other words, in the recognition that all these radiances are the emanations of one's own mind in a state of perfect tranquility and serenity, a state in which the mind reveals its true universal nature." (Govinda, op., cit., p. 262.)]

He will travel freely through many worlds or experience - from direct contact with life-process forms and images, he may pass to visions of human game-forms. He may see and understand with unimagined clarity and brilliance various social and self-games that he and others play. His own struggles in karmic (game) existence will appear pitiful and laughable. Ecstatic freedom of consciousness is the keynote of this vision. Exploration of unimagined realms. Theatrical adventures. Plays within plays within plays. Symbols change into things symbolized and vice versa. Words become things, thoughts are music, music is smelled, sounds are touched, complete interchangeability of the senses.

All things are possible. All feelings are possible. A person may "try on" various moods like so many pieces of clothing. Subjects and objects whirl, transform, change into each other, merge, fuse, disperse again. External objects dance and sing. The mind plays upon them as upon a musical instrument. They assume any form, significance or quality upon command. They are admired, adored, analyzed, examined, changed, made beautiful or ugly, large or small, important or trivial, useful, dangerous, magical or incomprehensible. They may be reacted to with wonder, amazement, humor, veneration, love, disgust, fascination, horror, delight, fear, ecstasy.

Like a computer with unlimited access to any programs, the mind roams freely. Personal and racial memories bubble up to the surface of consciousness, inter-play with fantasies, wishes, dreams and external objects. A present event becomes charged with profound emotional significance, a cosmic phenomenon becomes identical with some personal quirk. Metaphysical problems are juggled and bounced around. Pure "primary process," spontaneous outopouring of association, opposites merging, images fusing, condensing, shifting, collapsing, expanding, merging, connecting.

This kaleidoscopic vision of game-reality may be frightening and confusing to an ill-prepared subject. Instead of exquisite clarity of many-levelled perception, he will experience a confused chaos of uncontrollable, meaningless forms. Instead of delight at the playful acrobatics of the free intellect, there will be anxious clinging to an elusive order. Morbid and scatological hallucinations may occur, evoking disgust and shame.

As before, this negative vision occurs only if the person attempts to control or rationalize the magic panorama. Relax and accept whatever comes. Remember that all visions are created by your mind, the happy and the unhappy, the beautiful and the ugly, the delightful and the horrifying. Your consciousness is creator, performer and spectator of the "retinal circus."

If the guide senses that the voyager is in or seems to be in the "retinal circus" vision, he may read to him the appropriate instructions Instructions For Vision 6: "The Retinal Circus".

Vision 7: "The Magic Theatre"

If the voyager was unable to maintain the passive serenity necessary for the contemplation of the previous visions (the peaceful deities), he moves now into a more dramatic and active phase. The play of forms and things becomes the play of heroic figures, superhuman spirits and demigods. [In the Tibetan Handbook, this is described as the vision of the five "Knowledge- Holding Deities," arranged in a mandala form, each embraced by Dakinis, in an ecstatic dance. The Knowledge-holding Deities symbolize "the highest level of individual or humanly conceivable knowledge, as attained in the consciousness of great Yogis, inspired thinkers or similar heroes of the spirit. They represent the last step before the "breaking-through" towards the universal consciousness - or the first on the return from there to the plane of human knowledge." (Govinda, op. cit., p. 202.) The Dakinis are female embodiments of knowledge, representing the inspirational impulses of consciousness leading to break-through. The other four Knowledge-Holders, besides the central Lord of Dance, are: the Knowledge-holder abiding in the earth, the Knowledge-holder who has power over the duration of life, the Knowledge-holder of the Great Symbol, and the Knowledge-holder of Spontaneous Realization.] You may see radiating figures in human forms. The "Lotus Lord of Dance": the supreme image of a demi-god who perceives the effects of all actions. The prince of movement, dancing in an ecstatic embrace with his female counterpart. Heroes, heroines, celestial warriors, male and female demi-gods, angels, fairies - the exact form of these figures will depend on the person's background and tradition. Archetypal figures in the forms of characters from Greek, Egyptian, Nordic, Celtic, Aztec, Persian, Indian, Chinese mythology. The shapes differ, the source is the same: they are the concrete embodiments of aspects of the person's own psyche. Archetypal forces below verbal awareness and expressible only in symbolic form. The figures are often extremely colorful and accompanied by a variety of awe-inspiring sounds. If the voyager is prepared and in a relaxed, detached frame of mind, he is exposed to a fascinating and dazzling display of dramatic creativity. The Cosmic Theatre. The Divine Comedy. If his eyes are open, he may visualize the other voyagers as representing these figures. The face of a friend may turn into that of a young boy, a baby, the child-god; into a heroic stature, a wise old man; a woman, animal, goddess, sea-mother, young girl, nymph, elf, goblin, leprechaun. Images of the great painters arise as the familiar representations of these spirits. The images are inexhaustible and manifold. An illuminating voyage into the areas where the personal consciousness merges with the supr-individual.

The danger is that the voyager becomes frightened by or unduly attracted to these powerful figures. The forces represented by them may be more intense than he was prepared for. Inability or unwillingness to recognize them as products of one's mind, leads to escape into animalistic pursuits. The person may become involved in the pursuit of power, lust, wealth and descend into Third Bardo rebirth struggles.

If the guide senses that the voyager is caught in this trap, the appropriate instructions may be used: Instructions For Vision 7: "The Magic Theatre".

The Wrathful Visions
(Second Bardo Nightmares)

Seven Second Bardo visions have been described. At each one of them, the voyager could recognize what he saw and be liberated. Multitudes will be liberated by that recognition; and although multitudes obtain liberation in that manner, the number of sentient beings being great, evil karma powerful, obscurations dense, propensities of too long standing, the Wheel of Ignorance and Illusion becomes neither exhausted nor accelerated. Despite the confrontations, there is a vast preponderance of those who wander downwards unliberated.

Thus, in the Tibetan Thodo, after the seven peaceful deities, there come seven visions of wrathful deities, fifty-eight in number, male and female, "flame-enhaloed, wrathful, blood-drinking." These Herukas as they are called, will not be described in detail, especially since Westerners are liable to experience the wrathful deities in different forms. Instead of many-headed fierce mythological demons, they are more likely to be engulfed and ground by impersonal machinery, manipulated by scientific, torturing control-devices and other space-fiction horrors. [Some general remarks about the Tibetan interpretation of these visions. The Wrathful Deities are regarded as "only the former Peaceful Deities in changed aspect." Lama Govinda writes: "The peaceful forms of Dhyani-Buddhas represent the highest ideal of Buddhahood in its completed, final, static condition of ultimate attainment or perfection, seen retrospectively as it were, as a state of complete rest and harmony. The Herukas, on the other hand, which are described as "blood-drinking," angry or "terrifying" deities - are merely the dynamic aspect of enlightenment, the process of becoming a Buddha, of attaining illumination, as symbolized by the Buddha's struggle with the Hosts of Mara... . The ecstatic figures, heroic and terrifying, express the act of breaking through towards the unthinkable, the intellectually "Unattainable." They represent the leap over the chasm, which yawns between an intellectual surface consciousness and the intuitive supra-personal depth-consciousness." (Govinda, op. cit., pp. 198, 202.)]

The Tibetans regard the nightmare visions as primarily intellectual products. They assign them to the Brain chakra, whereas the peaceful deities are assigned to the Heart chakra and the Knowledge-Holding deities to the intermediate Throat chakra. They are the reactions of the mind to the process of consciousness-expansion. They represent the attempts of the intellect to maintain its threatened boundaries. They symbolize the struggle of breaking through to ego-loss understanding and awareness.

Because of the terror and awe they produce, recognition is difficult. Yet in a way it is also easier in that, since these negative hallucinations command all attention, the mind is alert and therefore through trying to escape from fear and terror, people get involved in psychotic states and suffer. But with the aid of this manual and the presence of a guide, the voyager will recognize these hell visions as soon as he sees them, and welcome them like old friends.

Again, when psychologists, philosophers, and psychiatrists, who do not know these teachings, experience ego-loss - however assiduously they may have devoted themselves to academic study and however clever they may have been in expounding intellectual theories - none of the higher phenomena will appear. This is because they are unable to recognize the visions occurring in these psychedelic experiences. Suddenly seeing something they had never seen before and possessing no intellectual concepts, they view it as inimical; and, antagonistic feelings arising, they pass into miserable states. Thus, if one has not had practical experience with these teachings, the radiances and lights will not appear.

Those who believe in these doctrines even though they may seem to be unrefined, irregular in performance of duties, inelegant in habits, and perhaps even unable to practice the doctrine successfully - let no one doubt them or be disrespectful towards them, but pay reverence to their mystic faith. That alone will enable them to attain liberation. Elegance and efficiency of devotional practice are not necessary - just acquaintance with and trust in these teachings.

Well-prepared persons need not experience Second Bardo hell visions at all. Right from the beginning they can pass into paradisiacal states led by heroes, heroines, angels and super-spirits. "They will merge into rainbow radiance; there will be sun-showers, sweet scent of incense in the air, music in the skies, radiances."

This manual is indispensable to those students who are unprepared. Those proficient in meditation will recognize the Clear Light at the moment of ego-loss and will enter the Blissful Void (Dharma-Kaya). They will also recognize the positive and negative visions of the Second Bardo and obtain illumination (Sambhogha-Kaya); and being reborn on a higher level will become inspired saints or teachers (Nirmana-Kaya). The study and pursuit of enlightenment can always be taken up again at the point where it was broken by the last ego-loss, thus ensuring continuity of karma.

By the use of this manual, enlightenment can be obtained without meditation, through hearing alone. It can liberate even very heavy ego-game players. The distinction between those who know it and those who do not becomes very clear. Enlightenment follows instantly. Those who have been reached by it cannot have prolonged negative experiences.

The teaching concerning the hell-visions is the same as before; recognize them to be your own thought-forms, relax, float downstream. The Instructions For The Wrathful Visions may be read. If, after this, recognition is still impossible and liberation is not obtained, then the voyager will descend into the Third Bardo, the Period of Re-Entry.

Conclusion Of Second Bardo

However much experience one may have had, there is always the possibility of delusions occurring in these psychedelic states. Those with practice in meditation recognize the truth as soon as the experience begins. Reading this manual beforehand is important. Having some degree of self-knowledge is helpful at the moment of ego-death.

Meditation on the various positive and negative archetypal forms is very important for Second Bardo phases. Therefore, read this manual, keep it, remember it, bear it in mind, read it regularly; let the words and meanings be very clear; they should not be forgotten, even under extreme duress. It is called "The Great Liberation by Hearing" because even those with selfish deeds on their conscience can be liberated if they hear it. If heard only once, it can be efficacious because even though not understood, it will be remembered during the psychedelic state, since the mind is more lucid then. It should be proclaimed to all living persons; it should be read over the pillows of ill persons; it should be read to dying persons; it should be broadcast.

Those who meet this doctrine are fortunate. It is not easy to encounter. Even when read, it is difficult to comprehend. Liberation will be won simply through not disbelieving it upon hearing it.

Here ends the Second Bardo the Period of Hallucinations.

Third Bardo: The Period Of Re-Entry (Sidpa Bardo)

Introduction into Third Bardo

If, in the second Bardo, the voyager is incapable of holding on to the knowledge that the peaceful and wrathful visions were projections of his own mind, but became attracted to or frightened by one or more of them, he will enter the Third Bardo. In this period he struggles to regain routine reality and his ego; the Tibetans call it the Bardo of "seeking rebirth." It is the period in which the consciousness makes the transition from transcendent reality to the reality of ordinary waking life. The teachings of this manual are of the utmost importance if one wishes to make a peaceful and enlightened re-entry and avoid a violent or unpleasant one.

In the original Bardo Thodol the aim of the teachings is "liberation," i.e., release from the cycle of birth and death. Interpreted esoterically, this means that the aim is to remain at the stage of perfect illumination and not to return to social game reality.

Only persons of extremely advanced spiritual development are able to accomplish this, by exercising the Transference Principle at the moment of ego-death. For average persons who undertake a psychedelic voyage, the return to game reality is inevitable. Such persons can and should use this part of the manual for the following purposes:

1. to free themselves from Third Bardo traps;
2. to prolong the session, thus assuring a maximum degree of illumination;
3. to select a favorable re-entry, i.e., to return to a wiser and more peaceful post-session personality.

Although no definite time estimates can be given, the Tibetans estimate that about 50% of the entire psychedelic experience is spent in the Third Bardo by most normal people. At times, as indicated in the Introduction, someone may move straight to the re-entry period if he is unprepared for or frightened by the ego-loss experiences of the first two Bardos.

The types of re-entry made can profoundly color the person's subsequent attitudes and feelings about himself and the world, for weeks or even months afterwards. A session which has been predominantly negative and fearful can still be turned to great advantage and much can be learned from it, provided the re-entry is positive and highly conscious. Conversely, a happy and revelatory experience can be made valueless by a fearful or negative re-entry.

The key instructions of the Third Bardo are: (1) do nothing, stay calm, passive and relaxed, no matter what happens; and (2) recognize where you are. If you do not recognize you will be driven by fear to make a premature and unfavorable re-entry. Only by recognizing can you maintain that state of calm, passive concentration necessary for a favorable re-entry. That is why so many recognition-points are given. If you fail on one, it is always possible, up to the very end, to succeed on another. Hence these teachings should be read carefully and remembered well.

In the following sections some of the characteristic Third Bardo experiences are described. In Part IV instructions are given appropriate to each section. At this stage in a psychedelic session the voyager is usually capable of telling the guide verbally what he is experiencing, so that the appropriate sections can be read. A wise guide can often sense the precise nature of the ego's struggle without words. The voyager will usually not experience all of these states, but only one or some of them; or sometimes the return to reality can take completely new and unusual turns. In such a case the general instructions for the Third Bardo should be emphasized: Third Bardo: Preliminary Instructions.

I. General Description of the Third Bardo

Normally, the person descends, step by step, into lower (more constricted) states of consciousness. Each step downwards may be preceded by a swooning into unconsciousness. Occasionally the descent may be sudden, and the person will find himself jolted back to a vision of reality which by contrast with the preceding phases seems dull, static, hard, angular, ugly and puppet-like. Such changes can induce fear and horror and he may struggle desperately to regain familiar reality. He may get trapped into irrational or even bestial perspectives which then dominate his entire consciousness. These narrow primitive elements stem from aspects of his personal history which are usually repressed. The more enlightened consciousness of the first two Bardos and the civilized elements of ordinary waking life are shelved in favor of powerful, obsessive primitive impulses, which in fact are merely faded and incoherent instinctual parts of the voyager's total personality. The suggestibility of Bardo consciousness makes them seem all-powerful and overwhelming.

On the other hand, the voyager may also feel that he possesses supernormal powers of perception and movement, that he can perform miracles, extraordinary feats of bodily control etc. The Tibetan book definitely attributes paranormal faculties to the consciousness of the Bardo voyager and explains it as due to the fact that the Bardo-consciousness encompasses future elements as well as past. Hence clairvoyance, telepathy, ESP, etc. are said to be possible. Objective evidence does not indicate whether this sense of increased perceptiveness is real or illusory. We therefore leave this as an open question, to be decided by empirical evidence.

This then is the first recognition point of the Third Bardo. The feeling of supernormal perception and performance. Assuming that it is valid, the manual warns the voyager not to be fascinated by his heightened powers, and not to exercise them. In yogic practice, the most advanced of the lamas teach the disciple not to strive after psychic powers of this nature for their own sake; for until the disciple is morally fit to use them wisely, they become a serious impediment to his higher spiritual development. Not until the selfish, game-involved nature of man is completely mastered is he safe in using them.

A second sign of Third Bardo existence are experiences of panic, torture and persecution. They are distinguished from the wrathful visions fo the Second Bardo in that they definitely seem to involve the person's own "skin-encapsulated ego." Mind-controlling manipulative figures and demons of hideous aspects may be hallucinated. The form that these torturing demons take will depend on the person's cultural background. Where Tibetans saw demons and beasts of prey, a Westerner may see impersonal machinery grinding, or depersonalizing and controlling devices of different futuristic varieties. Visions of world destruction, dying in space-fiction modes, and hallucinations of being engulfed by destructive powers will likewise come; and sounds of the mind-controlling apparatus, of the "combine's fog machinery," of the gears which move the scenery of the puppet show, of angry overflowing seas, and of the roaring fire and of fierce winds springing up, and of mocking laughter.

When these sounds and visions come, the first impulse will be to flee from them in panic and terror, not caring where one goes, so long as one goes out. In psychedelic drug experiences, the person may at this time plead or demand to be brought "out of it" through antidotes and tranquilizers. The person may see himself as about to fall down deep, terrifying precipices. These symbolize the so-called evil passions which, like narcotic drugs, enslave and bind mankind to existence in game-networks (sangsara): anger, lust, stupidity, pride or egoism, jealousy, and control-power. Such experiences, just as the previous one of enhanced power, should be regarded as recognizing features of the Third Bardo. One should neither flee the pain nor pursue the pleasure. Recognition is all that is necessary - and recognition depends upon preparation.

A third sign is a kind of restless, unhappy wandering which may be purely mental or may involve actual physical movement. The person feels as if driven by winds (winds of karma) or shunted around mechanically. There may be brief respites at certain places or scenes in the "ordinary" human world. Like a person travelling alone at night along a highway, having his attention arrested by prominent landmarks, great isolated trees, houses, bridgeheads, temples, hot-dog stands, etc., the person in the re-entry period has similar experiences. He may demand to return to familiar haunts in the human world. But any such external placation is temporary and soon the restless wandering will recommence. There may come a desperate desire to phone or otherwise contact your family, your doctor, your friends and appeal to them to pull you out of the state. This desire should be resisted. The guide and the fellow voyagers can be of best assistance. One should not try to involve others in one's hallucinatory world. The attempt will fail anyway since outsiders are usually unable to understand what is happening. Again, merely to recognize these desires as Third Bardo manifestations is already the first step toward liberation.

A fourth, rather common experience is the following: the person may feel stupid and full of incoherent thoughts, whereas everyone else seems to be perfectly knowing and wise. This leads to feelings of guilt and inadequacy and in extreme from to the Judgment Vision, to be described below. This feeling of stupidity is merely the natural result of the limited perspective under which the consciousness is operating in this Bardo. Calm, relaxed acceptance and trust will enable the voyager to win liberation at this point

Another experience, the fifth recognizing feature, which is especially impressive when it occurs suddenly, is the feeling of being dead, cut off from surrounding life, and full of misery. The person may with a jolt awake from some trance-like swoon and experience himself and the others as lifeless robots, performing wooden meaningless gestures. He may feel that he will never come back and will lament his miserable state.

Again, such fantasies are to be recognized as the attempts of the ego to regain control. In the true state of ego-death, as it occurs in the First or Second Bardos, such complaints are never uttered.

Sixth, one may have the feeling of being oppressed or crushed or squeezed into cracks and crevices amidst rocks and boulders. Or the person may feel that a kind of metallic net or cage may encompass him. This symbolizes the attempt prematurely to enter an ego-robot which is unfitting or unequipped to deal with the expanded consciousness. Therefore one should relax the panicky desire to regain an ego.

A Seventh aspect is a kind of grey twilight-like light suffusing everything, which is in marked contrast to the brilliantly radiating lights and colors of the earlier stages of the voyage. Objects, instead of shining, glowing and vibrating, are now dully colored, shabby and angular.

The passages Third Bardo: Preliminary Instructions contain general instructions for the Third Bardo state and its recognizable features. Any or all of the passages may be read when the guide senses that the voyager is beginning to return to the ego.

II. Re-entry Visions

In the preceding section the symptoms of re-entry were described, the signs that the voyager is trying to regain his ego. In this section are described visions of the types of re-entry one can make.

The Tibetan manual conceives of the voyager as returning eventually to one of six worlds of game existence (sangsara). That is, the re-entry to the ego can take place on one of six levels, or as one of six personality types. Two of these are higher than the normal human, three are lower. The highest, most illuminated, level is that of the devas, who are what Westerners would call saints, sages or divine teachers. They are the most enlightened people walking the earth. Gautama Buddha, Lao Tse, Christ. The second level is that of the asuras, who may be called titans or heroes, people with a more than human degree of power and vision. The third level is that of most normal human beings, struggling through game-networks, occasionally breaking free. The fourth level is that of primitive and animalistic incarnations. In this category we have the dog and the cock, symbolic of hyper-sexuality concomitant with jealousy; the pig, symbolizing lustful stupidity and uncleanliness; the industrious, hoarding ant; the insect or worm signifying an earthy or grovelling disposition; the snake, flashing in anger; the ape, full of rampaging primitive power; the snarling "wolf of the steppes;" the bird, soaring freely. Many more could be enumerated. In all cultures of the world people have adopted identities in the image of animals. In childhood and in dreams it is a process familiar to all. The fifth level is that of neurotics, frustrated lifeless spirits forever pursuing unsatisfied desires; the sixth and lowest level is hell or psychosis. Less than one percent of ego-transcendent experiences end in sainthood or psychosis. Most persons return to the normal human level.

According to The Tibetan Book of the Dead, each of the six game worlds or levels of existence is associated with a characteristic sort of thraldom, from which non-game experiences give temporary freedom: (1) existence as a deva, or saint, although more desirable than the others, is concomitant with an ever-recurring round of pleasure, free game ecstasy; (2) existence as an asura, or titan, is concomitant with incessant heroic warfare; (3) helplessness and slavery are characteristic of animal existence; (4) torments of unsatisfied needs and wants are characteristic of the existence of pretas, or unhappy spirits; (5) the characteristic impediments of human existence are inertia, smug ignorance, physical or psychological handicaps or various sorts.

According to the Bardo Thodol, the level one is detained for is determined by one's karma. During the period of the Third Bardo premonitory signs and visions of the different levels appear, that for which one is heading appearing most clearly. For example, the voyager may feel full of godlike power (asuras), or he may feel himself stirred by primitive or bestial impulses, or he may experience that all-pervasive frustration of the unhappy neurotics, or shudder at the tortures of a self-created hell.

The chances of making a favorable re-entry are increased if the process is allowed to take its own natural course, without effort or struggle. One should avoid pursuing or fleeing any of the visions, but meditate calmly on the knowledge that all levels exist in the Buddha also.

One can recognize and examine the signs as they appear and learn a great deal about oneself in a very short time. Although it is unwise to struggle against or flee the visions that come in this period, the Instructions For Re-entry Visions are designed to help the voyager regain First Bardo transcendence. In this way, if the person finds himself about to return to a personality or ego which he finds inappropriate to his new knowledge about himself, he can, by following the instructions, prevent this and make a fresh re-entry.

III. The All-Determining Influence of Thought

Liberation may be obtained, by such confrontation, even though previously it was not. If, however, liberation is not obtained even after these confrontations, further earnest and continued application is essential.

Should you feel attachment to material possessions, to old games and activities, or if you get any because other people are still involved in pursuits that you have renounced, this will affect the psychological balance in such a way that even if destined to return at a higher level, you will actually re-enter on a lower level in the world of unsatisfied spirits (neurosis). On the other hand, even if you do feel attached to worldly games that you have renounced, you will not be able to play them, and they will be of no use to you. Therefore abandon weakness and attachment to them; cast them away wholly; renounce them from your heart. No matter who may be enjoying your possessions, or taking your role, have no feelings of miserliness or jealousy, but be prepared to renounce them willingly. Think that you are offering them to your internal freedom and to your expanded consciousness. Abide in the feeling of non-attachment, devoid of weakness and craving.

Again, when the activities of the other members of the session are wrong, careless, inattentive or distracting, when the agreement or contract is broken, and when purity of intention is lost by any participant, and frivolity and laxness take over (all of which can clearly be seen by the Bardo voyager) you may feel lack of faith and begin to doubt your beliefs. You will be able to perceive any anxiety or fear, any selfish actions, ego-centric conduct and manipulative behavior. You may think: "Alas! they are playing me false, they have cheated and deceived." If you think thus, you will become extremely depressed, and through great resentment you will acquire disbelief and loss of faith, instead of affection and humble trust. Since this affects the psychological balance, re-entry will certainly be made on an unpleasant level.

Such thinking will not only be of no use, but it will do great harm. However improper the behavior of other, think thus: "What? How can the words of a Buddha be inappropriate? It is like the reflection of blemishes on my own face which I see in a mirror; my own thoughts must be impure. As for these others, they are noble in body, holy in speech, and the Buddha is within them: their actions are lessons for me."

Thus thinking, put your trust in your companions and exercise sincere love towards them. Then whatever they do will be to your benefit. The exercise of that love is very important; do not forget this!

Again, even if you were destined to return to a lower level and are already going into that existence, yet through the good deeds of friends, relatives, participants, learned teachers who devote themselves wholeheartedly to the correct performance of beneficent rituals, the delight from your feeling greatly cheered at seeing them will, by its own virtue, so affect the psychological balance that even though heading downwards, you may yet rise to a higher and happier level. Therefore you should not create selfish thoughts, but exercise pure affection and humble faith towards all, impartially. This is highly important. Hence be extremely careful.

The Instructions For The All-Determing Influence Of Thought are useful in any phase of the Third Bardo, but particularly if the voyager is reacting with suspicion or resentment to other members of the group, or to his own friends and relatives.

IV. Judgment Visions

The judgment vision may come: the Third Bardo blame game. "Your good genius will count up your good deeds with white pebbles, the evil genius the evil deeds with black pebbles." A judgment scene is a central part of many religious systems, and the vision can assume various forms. Westerners are most likely to see it in the well-known Christian version. The Tibetans give a psychological interpretation to this as to all the other visions. The Judge, or Lord of Death, symbolizes conscience itself in its stern aspect of impartiality and love of righteousness. The "Mirror of Karma" (the Christian Judgment Book), consulted by the Judge, is memory. Different parts of the ego will come forward, some offering lame excuses to meet accusations, others ascribing baser motives to various deeds, counting apparently neutral deeds among the black ones; still others offering justifications or requests for pardon. The mirror of memory reflects clearly; lying and subterfuge will be of no avail. Be not frightened, tell no lies, face truth fearlessly.

No you may imagine yourself surrounded by figures who wish to torment, torture or ridicule you (the "Executive Furies of the Robot Lord of Death"). These merciless figures may be internal or they may involve the people around you, seen as pitiless, mocking, superior. Remember that fear and guilt and persecuting, mocking figures are your own hallucinations. Your own guilt machine. Your personality is a collection of thought-patterns and void. It cannot be harmed or injured. "Swords cannot pierce it, fire cannot burn it." Free yourself from your own hallucinations. In reality there is no such thing as the Lord of Death, or a justice-dispensing god or demon or spirit. Act so as to recognize this.

Recognize that you are in the Third Bardo. Meditate upon your ideal symbol. If you do not know how to meditate, then merely analyze with great care the real nature of that which is frightening you: "Reality" is nothing but a voidness (Dharma-Kaya). That voidness is not of the voidness of nothingness, but a voidness at the true nature of which you feel awed, and before which your consciousness shines more clearly and lucidly. [That is the state of mind known as "Sambhoga-Kaya." In that state, you experience, with unbearable intensity, Voidness and Brightness inseparable - the Voidness bright by nature and the Brightness inseparable from the Voidness - a state of the primordial or unmodified consciousness, which is the Adi-Kaya. And the power of this, shining unobstructedly, will radiate everywhere; it is the Nirmana-Kaya.

These refer to the fundamental Wisdom Teachings of the Bardo Thodol. In all Tibetan systems of yoga, realization of the Voidness is the one great aim. To realize it is to attain the unconditioned Dharma-Kaya, or "Divine Body of Truth," the primordial state of uncreatedness, of the supra-mundane All-Consciousness. The Dharma-Kaya is the highest of the three bodies of the Buddha and of all Buddhas and beings who have perfect enlightenment. The other two bodies are the Sambhoga-Kaya or "Divine Body of Perfect Endowment" and the Nirmana-Kaya or "Divine Body of Incarnation." Adi-Kaya is synonymous with Dharma-Kaya. The Dharma-Kaya is primordial, formless Essential Wisdom; it is true experience freed from all error or inherent or accidental obscuration. It includes both Nirvana and Sangsara, which are polar states of consciousness, but in the realm of pure consciousness identical. The Sambhoga-Kaya embodies, as in the five Dhyani Buddhas, Reflected or Modified Wisdom; and the Nirmana-Kaya embodies, as in the Human Buddhas, Practical or Incarnate Wisdom. All enlightened beings who are reborn in this or any other world with full consciousness, as workers for the betterment of their fellow creatures, are said to be Nirmana-Kaya incarnates. Lama Kazi Dawa-Samdup, the translator of the Bardo Thodol, held that the Adi-Buddha, and all deities associated with the Dharma-Kaya, are not to be regarded as personal deities, but as personifications of primordial and universal forces, laws or spiritual influences. "In the boundless panorama of the existing and visible universe, whatever shapes appear, whatever sounds vibrate, whatever radiances illuminate, or whatever consciousnesses cognize, all are the play of manifestation in the Tri-Kaya, the Three-fold Principle of the Cause of All Causes, the Primordial Trinity. Impenetrating all, is the All-Pervading Essence of Spirit, which is Mind. It is uncreated, impersonal, self-existing, immaterial and indestructible." The Tri-Kaya is the esoteric trinity and corresponds to the exoteric trinity of Buddha, the Scriptures and the Priesthood (or your own divinity, this manual and your companions).

If the voyager is struggling with guilt and penance hallucinations, the Instructions For Judgment Visions may be read.

V. Sexual Visions

Sexual visions are extremely frequent during the Third Bardo. You may see or imagine males and females copulating. [According to Jung. ("Psychological Commentary" to The Tibetan Book of the Dead, Evans-Wentz edition, p. xiii), "Freud's theory is the first attempt made in the West to investigate, as if from below, from the animal sphere of instinct the psychic territory that corresponds in Tantric Lamaism to the Sidpa Bardo." The vision described here, in which the person sees mother and father in sexual intercourse, corresponds to the "primal scene" in psychoanalysis. At this level, then, we begin to see a remarkable convergence of Eastern and Western psychology. Note also the exact correspondence to the psychoanalytic theory of the Oedipus Complex.] This vision may be internal or it may involve the people around you. You may hallucinate multi-person orgies and experience both desire and shame, attraction and disgust. You may wonder what sexual performance is expected of you and have doubts about your ability to perform at this time.

When these visions occur, remember to withhold yourself from action or attachment. Have faith and float gently with the stream. Trust in the unity of life and in your companions.

If you attempt to enter into your old ego because you are attracted or repulsed, if you try to join or escape from the orgy you are hallucinating, you will re-enter on an animal or neurotic level. If you become conscious of "malness," hatred of the father together with jealousy and attraction towards the mother will be experienced; if you become conscious of "femaleness," hatred of the mother together with attraction and fondness for the father is experienced.

It is perhaps needless to say that this kind of self-centered sexuality has little in common with the sexuality of transpersonal experiences. Physical union can be one expression or manifestation of cosmic union.

Visions of sexual union may sometimes be followed by visions of conception - you may actually visualize the sperm uniting with the ovum - , of intra-uterine life and birth through the womb. Some people claim to have re-lived their own physical birth in psychedelic sessions and occasionally confirming evidence for such claims has been put forward. Whether this is so or not may be left as a question to be decided by empirical evidence. Sometimes the birth visions will be clearly symbolic - e.g., emergence from a cocoon, breaking out of a shell, etc.

Whether the birth vision is constructed from memory or fantasy, the psychedelic voyager should try to recognize the signs indicating the type of personality that is being reborn.

The Instructions For Sexual Visions may be read to the voyager who is struggling with sexual hallucinations.

VI. Methods for Preventing the Re-Entry

Although many confrontations and recognition points have been given, the person may be ill-prepared and still be wandering back to game reality. It is of advantage to postpone the return for as long as possible, thus maximizing the degree of enlightenment in the subsequent personality. For this reason four meditative methods are given for prolonging the ego-loss state. They are (1) meditation on the Buddha or guide; (2) concentration on good games; (3) meditation on illusion; and (4) meditation on the void. See the Four Methods Of Preventing Re-entry. Each one attempts to lead the voyager back to the First Bardo central stream of energy from which he has been separated by game involvements. One may ask how these meditative methods, which seem difficult for the ordinary person, can be effective. The answer given in the Tibetan Bardo Thodol is that due to the increased suggestibility and openness of the mind in the psychedelic state these methods can be used by anyone, regardless of intellectual capacity, or proficiency in meditation.

VII. Methods of Choosing the Post-Session Personality

Choosing the post-session ego is an extremely profound art and should not be undertaken carelessly or hastily. One should not return fleeing from hallucinated tormentors. Such re-entry will tend to bring the person to one of the three lower levels. One should first banish the fear by visualizing one's protective figure or the Buddha; then choose calmly and impartially.

The limited foreknowledge available to the voyager should be used to make a wise choice. In the Tibetan tradition each of the levels of game-existence is associated with a particular color and also certain geographical symbols. These may be different for twentieth-century Westerners. Each person has to learn to decode his own internal road map. The Tibetan indicators may be used as a starting point. The purpose is clear: one should follow the signs of the three higher types and shun those of the three lower. One should follow light and pleasant visions and shun dark and dreary ones.

The world of saints (devas) is said to shine with a white light and to be preceded by visions of delightful temples and jewelled mansions. The world of heroes (asuras) has a green light and is signalled by magical forests and fire images. The ordinary human world has a yellow light. Animal existence is foreshadowed by a blue light and images of caves and deep holes in the earth. The world of neurotics or unsatisfied spirits has a red light and visions of desolate plains and forest wastes. The hell world emits a smoke-colored light and is preceded by sounds of wailing, visions of gloomy lands, black and white houses and black roads along which you have to travel.

Use your foresight to choose a good post-session robot. Do not be attracted to your old ego. Whether you choose to pursue power, or status, or wisdom, or learning, or servitude, or whatever, choose impartially, without being attracted or repelled. Enter into game existence with good grace, voluntarily and freely. Visualize it as a celestial mansion, i.e., as an opportunity to exercise game-ecstasy. Have faith in the protection of the deities and choose. The mood of complete impartiality is important since you may be in error. A game that appears good may later turn out to be bad. Complete impartiality, freedom from want or fear, ensure that a maximally wise choice is made.

As you return you see spread out before you the world, your former life, a planet full of fascinating objects and events. Each aspect of the return trip can be a delightful discovery. Soon you will be descending to take your place in worldly events. The key to this return voyage is simply this: take it easy, slowly, naturally. Enjoy every second. Don't rush. Don't be attached to your old games. Recognize that you are in the re-entry period. Do not return with any emotional pressure. Everything you see and touch can glow with radiance. Each moment can be a joyous discovery.

Here end the Third Bardo, The Period of Re-Entry.

General Conclusion

Well-prepared students with advanced spiritual understanding can use the "Transference" principle at the moment of ego-death and need not traverse subsequent Bardo states. They will rise to a state of illumination and remain there throughout the entire period. Others, who are a little less experienced in spiritual discipline, will recognize the Clear Light in the second stage of the First Bardo and will then win liberation. Others, at a still less advanced level, may be liberated while experiencing one of the positive or negative visions of the Second Bardo. Since there are several turning points, liberation can be obtained at one or the other through recognition at moments of confrontation. Those of very weak karmic connection, i.e., those who have been involved in heavy ego-dominated game- playing, will have to wander downwards to the Third Bardo. Again, many points for liberation have been charted. The weakest persons will fall under the influence of guilt and terror. For weaker persons there are various graded teachings for preventing the return to routine-reality, or at least for choosing it wisely. Through applying the methods of visualization described, they should be able to experience the benefits of the session. Even those persons whose familiar routines are primitive and egocentric can be prevented from entering into misery. Once they have experienced, for however short a period, the great beauty and power of free awareness, they may, in the next period, meet with a guide or friend who will initiate them further into the way.

The way in which this teaching is effective, even for a voyager already in the Sidpa Bardo, is as follows: each person has some positive and some negative game-residues (karma). The continuity of consciousness has been broken by an ego-death for which the person was not prepared. The teachings are like a trough in a broken water drain, temporarily restoring the continuity with positive karma. As stated before, the extreme suggestibility or detached quality of consciousness in this state ensures the efficacy of listening to the doctrine. The teaching embedded in this Manual may be compared to a catapult which can direct the person towards the goal of liberation. Or like the moving of a big wooden beam, which is so heavy that a hundred men cannot carry it, but by being floated on water it can be easily moved. Or it is like controlling a horse's bit and course by the use of a bridle.

Therefore, these teachings should be vividly impressed on the voyager, again and again. This Manual may also be used more generally. It should be recited as often as possible and committed to memory as far as possible. When ego-death or final death comes, recognize the symptoms, recite the Manual to yourself, and reflect upon the meaning. If you cannot do it yourself, ask a friend to read it to you. There is no doubt as to its liberative power.

It liberates by being seen or heard, without need of ritual or complex meditation. This Profound Teaching liberates those of great evil karma through the Secret Pathway. One should not forget its meaning and the words, even though pursued by seven mastiffs. By this Select Teaching, one obtains Buddhahood at the moment of ego-loss. Were the Buddhas of past, present and future to seek, they could not find any doctrine transcending this.

Here ends the Bardo Thodol, known as The Tibetan Book of the Dead.

III. Some Technical Comments About Psychedelic Sessions

1. Use of This Manual

The most important use of this manual is for preparatory reading. Having read the Tibetan Manual, one can immediately recognize symptoms and experiences which might otherwise be terrifying, only because of lack of understanding as to what was happening. Recognition is the key word.

Secondly, this guidebook may be used to avoid paranoid traps or to regain the First Bardo transcendence if it has been lost. If the experience starts with light, peace, mystic unity, understanding, and if it continues along this path, then there is no need to remember this manual of have this manual re-read to you. Like a road map, we consult it only when lost, or when we wish to change course. Usually, however, the ego clings to its old games. There may be momentary discomfort or confusion. If this happens, the others present should not be sympathetic or show alarm. They should be prepared to stay calm and restrain their "helping games." In particular, the "doctor" role should be avoided.

If at any time you find yourself struggling to get back to routine reality, you can (by pre-arrangement) have a more experienced person, a fellow-voyager, or a trusted observer read parts of this manual to you.

Passages suitable for reading during the session are given in Part IV below. Each major descriptive section of the Tibetan Book has an appropriate instruction text. One may want to pre-record selected passages and simply flick on the recorder when desired. The aim of these instruction texts is always to lead the voyager back to the original First Bardo transcendence and to help maintain that as long as possible.

A third use would be to construct a "program" for a session using passages from the text. The aim would be to lead the voyager to one of the visions deliberately, or through a sequence of visions. The guide or friend could read the relevant passages, show slides or pictures or symbolic figures of processes, play carefully selected music, etc. One can envision a high art of programming psychedelic sessions, in which symbolic manipulations and presentations would lead the voyager through ecstatic visionary Bead Games.

2. Planning a Session

In planning a session, the first question to be decided is "what is the goal?" Classic Hinduism suggest four possibilities:

(1) For increased personal power, intellectual understanding, sharpened insight into self and culture, improvement of life situation, accelerated learning, professional growth.

(2) For duty, help of others, providing care, rehabilitation, rebirth for fellow men.

(3) For fun, sensuous enjoyment, aesthetic pleasure, interpersonal closeness, pure experience.

(4) For transcendence, liberation from ego and space-time limits; attainment of mystical union.

This manual aims primarily at the latter goal - that of liberation-enlightenment. This emphasis does not preclude attainment of the other goals - in fact, it guarantees their attainment because illumination requires that the person be able to step out beyond game problems of personality, role, and professional status. The initiate can decide beforehand to devote the psychedelic experience to any of the four goals. The manual will be of assistance in any event.

If there are several people having a session together they should either agree collaboratively on a goal, or at least be aware of each other's goals. If the session is to be "programmed" then the participants should either agree on or design a program collaboratively, or they should agree to let one member of the group do the programming. Unexpected or undesired manipulations by one of the participants can easily "trap the other voyagers into paranoid Third Bardo delusions.

The voyager, especially in an individual session, may also wish to have either an extroverted or an introverted experience. In the extroverted transcendent experience, the self is ecstatically fused with external objects (e.g. flowers, or other people). In the introverted state, the self is ecstatically fused with internal life processes (lights, energy-waves, bodily events, biological forms, etc.). Of course, either the extroverted or the introverted state may be negative rather than positive, depending on the attitude of the voyager. Also it may be primarily conceptual or primarily emotional. The eight types of experience thus derived (four positive and four negative) have been described more fully in Visions 2 to 5 of the Second Bardo.

For the extroverted mystic experience one would bring to the session objects or symbols to guide the awareness in the desired direction. Candles, pictures, books, incense, music or recorded passages. An introverted mystic experience requires the elimination of all stimulation; no light, no sound, no smell, no movement.

The mode of communication with the other participants should also be agreed on beforehand. You may agree on certain signals, silently indicating companionship. You may arrange for physical contact - clasping hands, embracing. These means of communication should be pre-arranged to avoid game-misinterpretations that may develop during the heightened sensitivity of ego-transcendence.

3. Drugs and Dosages

A wide variety of chemicals and plants have psychedelic ("mind manifesting") effects. The most widely used substances are listed here together with dosages adequate for a normal adult of average size. The dosage to be taken depends, of course, on the goal of the session. Two figures are therefore given. The first column indicates a dosage which should be sufficient for an inexperienced person to enter the transcendental worlds described in this manual. The second column gives a smaller dosage figure, which may be used by more experienced persons or by participants in a group session.

- LSD-25 (lysergic acid diethylamide) 200-500 micrograms 100-200 micrograms
- Mescaline 600-800 mg 300-500 mg
- Psilocybin 40-60 mg 20-30 mg

The time of onset, when the drugs are taken orally on an empty stomach, is approximately 20-30 minutes for LSD and psilocybin, and one to two hours for mescaline. The duration of the session is usually eight to ten hours for LSD and mescaline, and five to six hours for psilocybin. DMT (dimethyltryptamine), when injected intramuscularly in dosages of 50-60 mg, gives an experience approximately equivalent to 500 micrograms of LSD, but which lasts only 30 minutes.

Some person have found it useful to take other drugs before the session. A very anxious person, for example, may take 30 to 40 mg of Librium about on hour earlier, to calm and relax himself. Methedrine has also been used to induced a pleasant, euphoric mood prior to the session. Sometimes, with excessively nervous persons, it is advisable to stagger the drug administration: for example, 200 micrograms of LSD may be taken initially, and a "booster" of another 200 micrograms may be taken after the person has become familiar with some of the effects of the psychedelic state. Nausea may sometimes occur. Usually this is a mental symptom, indicating fear, and should be regarded as such. Sometimes, however, particularly with the use of morning-glory seeds and peyote, the nausea can have a physiological cause. Anti-nauseant drugs such as Marezine, Bonamine, Dramamine or Tigan, may be taken beforehand to prevent this.

If a person becomes trapped in a repetitive game-routine during a session, it is sometimes possible to "break the set" by administering 50 mg of DMT, or even 25 mg of Dexedrine or Methedrine. Such additional dosages, of course, should only be given with the person's own knowledge and consent.

Should external emergencies call for it, Thorazine (100-200 mg, i.m.) or other phenothiazine-type tranquilizers will terminate the effects of psychedelic drugs. Antidotes should not be used simply because the voyager or the guide is frightened. Instead, the appropriate sections of the Third Bardo should be read. [Further, more detailed suggestions concerning dosage may be found in a paper by Gary M. Fisher: "Some Comments Concerning Dosage Levels of Psychedelic Compounds for Psychotherapeutic Experiences." Psychedelic Review, I, no.2, pp. 208-218, 1963.]

4. Preparation

Psychedelic chemicals are not drugs in the usual sense of the word. There is no specific reaction, no expected sequence of events, somatic or psychological.

The specific reaction has little to do with the chemical and is chiefly a function of set and setting; preparation and environment. The better the preparation, the more ecstatic and revelatory the session. In initial sessions and with unprepared persons, setting - particularly the actions of others - is most important. With persons who have prepared thoughtfully and seriously, the setting is less important.

There are two aspects of set: long-range and immediate.

Long-range set refers to the personal history, the enduring personality. The kind of person you are - your fears, desires, conflicts, guilts, secret passions - determines how you interpret and manage any situation you enter, including a psychedelic session. Perhaps more important are the reflex mechanisms used when dealing with anxiety - the defenses, the protective maneuvers typically employed. Flexibility, basic trust, religious faith, human openness, courage, interpersonal warmth, creativity, are characteristics which allow for fun and easy learning. Rigidity, desire to control, distrust, cynicism, narrowness, cowardice, coldness, are characteristics which make any new situation threatening. Most important is insight. No matter how many cracks in the record, the person who has some understanding of his own recording machinery, who can recognize when he is not functioning as he would wish, is better able to adapt to any challenge - even the sudden collapse of his ego.

The most careful preparation would include some discussion of the personality characteristics and some planning with the guide as to how to handle expected emotional reactions when they occur.

Immediate set refers to the expectations about the session itself. Session preparation is of critical importance in determining how the experience unfolds. People tend naturally to impose their personal and social game perspectives on any new situation. Careful thought should precede the session to prevent narrow sets being imposed.

Medical expectations. Some ill-prepared subjects unconsciously impose a medical model on the experience. They look for symptoms, interpret each new sensation in terms of sickness/health, place the guide in a doctor-role, and, if anxiety develops, demand chemical rebirth - i.e., tranquilizers. Occasionally one hears of casual, ill-planned, non-guided sessions which end in the subject demanding to be hospitalized, etc. It is even more problem-provoking if the guide employs a medical model, watches for symptoms, and keeps hospitalization in mind to fall back on, as protection for himself.

Rebellion against convention may be the motive of some people who take the drug. The idea of doing something "far out" or vaguely naughty is a naive set which can color the experience.

Intellectual expectations are appropriate when subjects have had much psychedelic experience. Indeed, LSD offers vast possibilities for accelerated learning and scientific-scholarly research. But for initial sessions, intellectual reactions can become traps. The Tibetan Manual never tires of warning about the dangers of rationalization. "Turn you mind off" is the best advice for novitiates. Control of your consciousness is like flight instruction. After you have learned how to move your consciousness around - into ego-loss and back, at will - then intellectual exercises can be incorporated into the psychedelic experience. The last stage of the session is the best time to examine concepts. The objective of this particular manual is to free you from you verbal mind for as long as possible.

Religious expectations invite the same advice as intellectual set. Again, the subject in early sessions is best advised to float with the stream, stay "up" as long as possible, and postpone theological interpretations until the end of the session, or to later sessions.

Recreational and aesthetic expectations are natural. The psychedelic experience, without question, provides ecstatic moments which dwarf any personal or cultural game. Pure sensation can capture awareness. Interpersonal intimacy reaches Himalayan heights. Aesthetic delights - musical, artistic, botanical, natural -

are raised to the millionth power. But all these reactions can be Third Bardo ego games: "I am having this ecstasy. How lucky I am!" Such reactions can become tender traps, preventing the subject from reaching pure ego-loss (First Bardo) or the glories of Second Bardo creativity.

Planned expectations. This manual prepares the person for a mystical experience according to the Tibetan model. The Sages of the Snowy Ranges have developed a most sophisticated and precise understanding of human psychology, and the student who studies this manual will become oriented for a voyage which is much richer in scope and meaning than any Western psychological theory. We remain aware, however, that the Bardo Thodol model of consciousness is a human artifact, a Second Bardo hallucination, however grand its scope.

Some practical recommendations. The subject should set aside at least three days for his experience; a day before, the session day, and a follow-up day. This scheduling guarantees a reduction in external pressure and a more sober commitment to the voyage.

Talking to others who have taken the voyage is excellent preparation, although the Second Bardo hallucinatory quality of all descriptions should be recognized. Observing a session is another valuable preliminary. The opportunity to see others during and after a session shapes expectations.

Reading books about mystical experience is a standard orientation procedure. Reading the accounts of others' experiences is another possibility (Aldous Huxley, Alan Watts, and Gordon Wasson have written powerful accounts).

Meditation is probably the best preparation for a psychedelic session. Those who have spent time in the solitary attempt to manage the mind, to eliminate thought and to reach higher stages of concentration, are the best candidates for a psychedelic session. When the ego-loss state occurs, they are ready. They recognize the process as an end eagerly awaited, rather than a strange event ill-understood.

5. The Setting

The first and most important thing to remember, in the preparation for a psychedelic session, is to provide a setting which is removed from one's usual social and interpersonal games and which is as free as possible from unforeseen distractions and intrusions. The voyager should make sure that he will not be disturbed by visitors or telephone calls, since these will often jar him into hallucinatory activity. Trust in the surroundings and privacy are necessary.

A period of time (usually at least three days) should be set aside in which the experience will run its natural course and there will be sufficient time for reflections and meditation. It is important to keep schedules open for three days and to make these arrangements beforehand. A too-hasty return to game-involvements will blur the clarity of the vision and reduce the potential for learning. If the experience was with a group, it is very useful to stay together after the session in order to share and exchange experiences.

There are differences between night sessions and day sessions. Many people report that they are more comfortable in the evening and consequently that their experiences are deeper and richer. The person should choose the time of day that seems right according to his own temperament at first. Later, he may wish to experience the difference between night and day sessions.

Similarly, there are differences between sessions out-of-doors and indoors. Natural settings such as gardens, beaches, forests, and open country have specific influences which one may or may not wish to incur. The essential thing is to feel as comfortable as possible in the surroundings, whether in one's living room or under the night sky. A familiarity with the surroundings may help one to feel confident in hallucinatory periods. If the session is held indoors, one must consider the arrangement of the room and the specific objects one may wish to see and hear during the experience.

Music, lighting, the availability of food and drink, should be considered beforehand. Most people report no desire for food during the height of the experience, and then, later on, prefer to have simple, ancient foods like bread, cheese, wine, and fresh fruit. Hunger is usually not the issue. The senses are wide open, and the taste and smell of a fresh orange are unforgettable.

In group sessions, the arrangement of the room is quite important. People usually will not feel like walking or moving very much for a long period, and either beds or mattresses should be provided. The arrangement of the beds or mattresses can vary. One suggestion is to place the heads of the beds together to form a star pattern. Perhaps one may want to place a few beds together and keep one or two some distance apart for anyone who wishes to remain aside for some time. Often, the availability of an extra room is desirable for someone who wishes to be in seclusion for a period.

If it is desired to listen to music or to reflect on paintings or religious objects, one should arrange these so that everyone in the group feels comfortable with what they are hearing or seeing. In a group session, all decisions about goals, setting, etc. should be made with collaboration and openness.

6. The Psychedelic Guide

For initial sessions, the attitude and behavior of the guide are critical factors. He possesses enormous power to shape the experience. With the cognitive mind suspended, the subject is in a heightened state of suggestibility. The guide can move consciousness with the slightest gesture or reaction.

The key issue here is the guide's ability to turn off his own ego and social games - in particular, to muffle his own power needs and his fears. To be there relaxed, solid, accepting, secure. The Tao wisdom of creative quietism. To sense all and do nothing except to let the subject know your wise presence.

A psychedelic session lasts up to twelve hours and produces moments of intense, intense, INTENSE reactivity. The guide must never be bored, talkative, intellectualizing. He must remain calm during the long periods of swirling mindlessness.

He is the ground control in the airport tower. Always there to receive messages and queries from high-flying aircraft. Always ready to help navigate their course, to help them reach their destination. An airport-tower-operator who imposes his own personality, his own games upon the pilot is unheard of. The pilots have their own flight plan, their own goals, and ground control is there, ever waiting to be of service.

The pilot is reassured to know that an expert who has guided thousands of flights is down there, available for help. But suppose the flier has reason to suspect that ground control is harboring his own motives and might be manipulating the plane toward selfish goals. The bond of security and confidence would crumble.

It goes without saying, then, that the guide should have had considerable experience in psychedelic sessions himself and in guiding others. To administer psychedelics without personal experience is unethical and dangerous.

The greatest problem faced by human beings in general, and the psychedelic guide in particular, is fear. Fear of the unknown. Fear of losing control. Fear of trusting the genetic process and your companions. From our own research studies and our investigations into sessions run by others - serious professionals or adventurous bohemians - we have been led to the conclusion that almost every negative LSD reaction has been caused by fear on the part of the guide which has augmented the transient fear of the subject. When the guide acts to protect himself, he communicates his concern to the subject.

The guide must remain passively sensitive and intuitively relaxed for several hours. This is a difficult assignment for most Westerners. For this reason, we have sought ways to assist the guide in maintaining a state of alert quietism in which he is poised with ready flexibility. The most certain way to achieve this state is for the guide to take a low dose of the psychedelic with the subject. Routine procedure is to have one trained person participate in the experience and one staff member present in ground control without psychedelic aid.

The knowledge that one experienced guide is "up" and keeping the subject company, is of inestimable value; intimacy and communication; cosmic companionship; the security of having a trained pilot flying at your wing tip; the scuba diver's security in the presence of an expert comrade in the deep.

It is not recommended that guides take large doses during sessions for new subjects. The less experienced he is, the more likely will the subject impose Second and Third Bardo hallucinations. These intense games affect the experienced guide, who is likely to be in a state of mindless void. The guide is then pulled into the hallucinatory field of the subject, and may have difficulty orienting himself. During the First Bardo there are no familiar fixed landmarks, no place to put your foot, no solid concept upon which to base your thinking. All is flux. Decisive Second Bardo action on the part of the subject can structure the guide's flow if he has taken a heavy dose.

The role of the psychedelic guide is perhaps the most exciting and inspiring role in society. He is literally a liberator, one who provides illumination, one who frees men from their life-long internal bondage. To be present at the moment of awakening, to share the ecstatic revelation when the voyager discovers the wonder and awe of the divine life-process, is for many the most gratifying part to play in the evolutionary drama. The role of the psychedelic guide has a built-in protection against professionalism and didactic oneupmanship. The psychedelic liberation is so powerful that it far outstrips earthly game ambitions. Awe and gratitude - rather than pride - are the rewards of this new profession.

7. Composition of the Group

The most effective use of this manual will be for the experience of one person with a guide. However, the manual will be useful in a group also. When used in a group session, the following suggestions will be most helpful in planning.

The important thing to remember in organizing a group session is to have knowledge of and trust in the fellow voyagers. Trust in oneself and in one's companions is essential. If preparing for an experience with strangers, it is very important to share as much time and space as possible with them prior to the session. The participants should set collaborative goals and explore mutually their expectations and feelings and past experiences.

The size of the group should depend to some extent on how much experience the participants have had. Initially, small groups are preferable to larger ones. In any case, group experiences exceeding six or seven people are demonstrably less profound and generate more paranoid hallucinations. If planning for a group session of five or six people, it is preferable to have at least two guides present. One will take the psychedelic substance and the other, who does not, serves as a practical guide to take care of such concerns as changing the recordings, providing food, etc., and if necessary or desired, reading selections from the manual. If it is possible, one of the guides should be an experienced woman who can provide an atmosphere of spiritual nurturing and comfort.

It is sometimes advisable that the initial session of married couples be separate in order that the exploration of their marriage game not dominate the session. With some experience in consciousness-expansion, the marriage game like others may be explored for any purpose - increased intimacy, clearer communication, exploration of the foundations of the sexual, mating relationship, etc.

IV. Instructions For Use During A Psychedelic Session

First Bardo Instructions

O (name of voyager)
The time has come for you to seek new levels of reality.
Your ego and the (name) game are about to cease.
Your are about to be set face to face with the Clear Light
Your are about to experience it in its reality.
In the ego-free state, wherein all things are like the void and cloudless sky,
And the naked spotless intellect is like a transparent vacuum;
At this moment, know yourself and abide in that state.

O (name of voyager),
That which is called ego-death is coming to you.
Remember:
This is now the hour of death and rebirth;
Take advantage of this temporary death to obtain the perfect state -
Enlightenment.
Concentrate on the unity of all living beings.
Hold onto the Clear Light.
Use it to attain understanding and love.

If you cannot maintain the bliss of illumination and if you are slipping back
into contact with the external world,
Remember:
The hallucinations which you may now experience,
The visions and insights,
Will teach you much about yourself and the world.
The veil of routine perception will be torn from you eyes.
Remember the unity of all living things.
Remember the bliss of the Clear Light.
Let it guide you through the visions of this experience.
Let it guide you through your new life to come.
If you feel confused; call upon the memory of your friends and the power of
the person whom you most admire.

O (name),
Try to reach and keep the experience of the Clear Light.
Remember:
The light is the life energy.
The endless flame of life.
An ever-changing surging turmoil of color may engulf your vision.
This is the ceaseless transformation of energy.
The life process.
Do not fear it.
Surrender to it.
Join it.
It is part of you.
You are part of it.
Remember also:
Beyond the restless flowing electricity of life is the ultimate reality -
The Void.
Your own awareness, not formed into anything possessing form or color,
is naturally void.

The Final Reality.
The All Good.
The All Peaceful.
The Light.
The Radiance.
The movement is the fire of life from which we all come.
Join it.
It is part of you.
Beyond the light of life is the peaceful silence of the void.
The quiet bliss beyond all transformations.
The Buddha smile.
The Void is not nothingness.
The Void is beginning and end itself.
Unobstructed; shining, thrilling, blissful.
Diamond consciousness.
The All-Good Buddha.
Your own consciousness, not formed into anything,
No thought, no vision, no color, is void.
The intellect shining and blissful and silent -
This is the state of perfect enlightenment.
Your own consciousness, shining, void and inseparable from the great body
of radiance, has no birth, nor death.
It is the immutable light which the Tibetans call Buddha Amitabha,
The awareness of the formless beginning.
Knowing this is enough.
Recognize the voidness of your own consciousness to be Buddhahood.
Keep this recognition and you will maintain the state of the divine mind
of the Buddha.

Second Bardo Preliminary Instructions

Remember:
In this session you experience three Bardos,
Three states of ego-loss.
First there is the Clear Light of Reality.
Next there are fantastically varied game hallucinations.
Later you will reach the stage of Re-Entry
Of regaining an ego.

O friend,
You may experience ego-transcendence,
Departure from your old self.
But you are not the only one.
It comes to all at some time.
You are fortunate to have this gratuitously given rebirth experience.
Do not cling in fondness and weakness to your old self.
Even though you cling to your mind, you have lost the power to keep it.
You can gain nothing by struggling in this hallucinatory world.
Be not attached.
Be not weak.
Whatever fear or terror may come to you
Forget not these words.
Take their meaning into your heart.
Go forward.
Herein lies the vital secret of recognition.

O friend, remember:
When body and mind separate, you experience a glimpse of the pure truth -
Subtle, sparkling, bright,
Dazzling, glorious, and radiantly awesome,
In appearance like a mirage moving across a landscape in springtime.
One continuous stream of vibrations.
Be not daunted thereby,
Nor terrified, nor awed.
That is the radiance of your own true nature.
Recognize it.

From the midst of that radiance
Comes the natural sound of reality,
Reverberating like a thousand thunders simultaneously sounding.
That is the natural sound of your own life process.
Be not daunted thereby,
Nor terrified, nor awed.
It is sufficient for you to know that these apparitions are your own thought-forms.
If you do not recognize your own thought forms,
If you forget your preparation,
The lights will daunt you,
The sounds will awe you,
The rays will terrify you,
The people around you will confuse you.
Remember the key to the teachings.

O friend,
These realms are not come from somewhere outside your self,
They come from within and shine upon you.
The revelations too are not come from somewhere else;
They exist from eternity within the faculties of your own intellect.
Know them to be of that nature.

The key to enlightenment and serenity during this period of ten thousand
visions is simply this:
Relax.
Merge yourself with them.
Blissfully accept the wonders of your own creativity.
Become neither attached nor afraid,
Neither be attracted nor repulsed.
Above all, do nothing about the visions.
They exist only within you.

Instructions For Vision 1: The Source
(Eyes closed, external stimuli ignored)

O nobly-born, listen carefully:
The Radiant Energy of the Seed
From which come all living forms,
Shoots forth and strikes against you
With a light so brilliant that you will scarcely be able to look at it.
Do not be frightened.
This is the Source Energy which has been radiating for billions of years,
Ever manifesting itself in different forms.
Accept it.
Do not try to intellectualize it.

Do not play games with it.
Merge with it.
Let it flow through you.
Lose yourself in it.
Fuse in the Halo of Rainbow Light
Into the core of the energy dance.
Obtain Buddhahood in the Central Realm of the Densely Packed.

Instructions For Physical Symptoms

O friend, listen carefully.
The bodily symptoms you are having are not drug-effects.
They indicate that you are struggling against the awareness of feelings which surpass your normal experience.
You cannot control these universal energy-waves.
Let the feelings melt all over you.
Become part of them.
Sink into them and through them.
Allow yourself to pulsate with the vibrations surrounding you.
Relax.
Do not struggle.
Your symptoms will disappear as soon as all trace of ego-centered striving disappears.
Accept them as the message of the body.
Welcome them. Enjoy them.

Instructions For Vision 2: The Internal Flow Of Archetypal Processes
(Eyes closed, external stimuli ignored; intellectual aspects)

O nobly born, listen carefully:
The life flow is whirling through you.
An endless parade of pure forms and sounds,
Dazzlingly brilliant,
Ever-changing.
Do not try to control it.
Flow with it.
Experience the ancient cosmic myths of creation and manifestation.
Do not try to understand;
There is plenty of time for that later.
Merge with it.
Let it flow through you.
There is no need to act or think.
You are being taught the great lessons of evolution, creation, reproduction.
If you try to stop it, you may fall into hell-worlds and endure unbearable misery generated by your own mind.
Avoid game interpretations.
Avoid thinking, talking and doing.
Keep faith in the life flow.
Trust your companions on this watery journey.
Merge in Rainbow Light,
Into the Heart of The River of Created Forms.
Obtain Buddhahood in the Realm called Pre-Eminently Happy.

Instructions For Vision 3: The Fire-Flow Of Internal Unity (Eyes closed, external stimuli ignored, emotional aspects)

O nobly born, listen carefully:
You are flowing outward into the fluid unity of life.
The ecstasy of organic fire glows in every cell.
The hard, dry, brittle husks of your ego are washing out,
Washing out to the endless sea of creation.
Flow with it.
Feel the pulse of the sun's heart.
Let the red Buddha Amitabha sweep you along.
Do not fear the ecstasy.
Do not resist the flow.
Remember, all the exultant power comes from within.
Release your attachment.
Recognize the wisdom of your own blood.
Trust the tide-force pulling you into unity with all living forms.
Let your heart burst in love for all life.
Let your warm blood gush out into the ocean of all life.
Do not be attached to the ecstatic power;
It comes from you.
Let it flow.
Do not try to hold on to your old bodily fears.
Let your body merge with the warm flux.
Let your roots sink into the warm life body.
Merge into the Heart-Glow of the Buddha Amitabha.
Float in the Rainbow Sea.
Attain Buddhahood in the Realm named Exultant Love.

Instructions For Vision 4: The Wave-Vibration Structure Of External Forms (Eyes open, rapt involvement with the external visual stimuli, intellectual aspects)

O nobly born, listen carefully:
At this point you can become aware of the wave structure of the world around you.
Everything you see dissolves into energy vibrations.
Look closely and you will tune in on the electric dance of energy.
There are no longer things and persons but only the direct flow of particles.
Consciousness will now leave your body and flow into the stream of wave rhythm.
There is no need for talk or action.
Let your brain become a receiving set for the radiance.
All interpretations are the products of your own mind.
Dispel them. Have no fear.
Exult in the natural power of your own brain,
The wisdom of your own electricity.
Abide in the state of quietude.
As the three-dimensional world fragments, you may feel panic;
You may beget a fondness for the heavy dull world of objects you are leaving.
At this time, fear not the transparent, radiant, dazzling wave energy.

Allow your intellect to rest.
Fear not the hook-rays of the light of life,
The basic structure of matter,
The basic form of wave communication.
Watch quietly and receive the message.
You will now experience directly the revelation of primal forms.

Instructions For Vision 5: The Vibratory Waves Of External Unity (Eyes open; rapt involvement with external stimuli such as lights, or movements; emotional aspects)

O nobly born, listen carefully:
You are experiencing the unity of all living forms.
If people seem to you rubbery and lifeless, like plastic puppets,
Be not afraid.
This is only the attempt of the ego to maintain its separate identity.
Allow yourself to feel the unity of all.
Merge with the world around you.
Be not afraid.
Enjoy the dance of the puppets.
They are created by your own mind.
Allow yourself to relax and feel the ecstatic energy-vibrations pulsing through you.
Enjoy the feeling of complete one-ness with all life and all matter.
The glowing radiance is a reflection of your own consciousness.
It is one aspect of your divine nature.
Do not be attached to your old human self.
Do not be alarmed at the new and strange feelings you are having.
If you are attracted to your old self,
You will be reborn shortly for another round of game-existence.
Exercise humble trust and remain fearless.
You will merge into the heart of the Blessed Ratnasambhava,
In a Halo of Rainbow Light,
And attain liberation in the Realm Endowed with Glory.

Instructions For Vision 6: "The Retinal Circus"

O nobly born, listen well:
You are now witnessing the magical dance of forms.
Ecstatic kaleidoscopic patterns explode around you.
All possible shapes come to life before you eyes.
The retinal circus.
The ceaseless play of elements -
Earth, water, air, fire,
In ever-changing forms and manifestations,
Dazzles you with its complexity and variety.
Relax and enjoy the rushing stream.
Do not become attached to any vision or revelation.
Let everything flow through you.
If unpleasant experiences come,
Let them flit by with the rest.
Do not struggle against them.
It all comes from within you.
This is the great lesson in the creativity and power of the brain, freed from

its learned structures.
Let the cascade of images and associations take you where it will.
Meditate calmly on the knowledge that all these visions are emanations of your own consciousness.
This way you can obtain self-knowledge and be liberated.

Instructions For Vision 7: "The Magic Theatre"

O nobly born, listen well:
You are now in the magic theatee of heroes and demons.
Mythical superhuman figures.
Demons, goddesses, celestial warriors, giants,
Angels, Bodhisattvas, dwarfs, crusaders,
Elves, devils, saints, and sorcerers,
Infernal spirits, goblins, knights and emperors.
The Lotus Lord of Dance.
The Wise Old Man. The Divine Child.
The Trickster, The Shapeshifter.
The tamer of monsters.
The mother of gods, the witch.
The moon king. The wanderer.
The whole divine theater of figures representing the highest reaches of human knowledge.
Do not be afraid of them.
They are within you.
Your own creative intellect is the master magician of them all.
Recognize the figures as aspects of your self.
The whole fantastic comedy takes place within you.
Do not become attached to the figures.
Remember the teachings.
You may still attain liberation.

Instructions For The Wrathful Visions

O nobly born, listen carefully:
You were unable to maintain the perfect Clear Light of the First Bardo.
Or the serene peaceful visions of the Second.
You are now entering Second Bardo nightmares.
Recognize them.
They are your own thought-forms made visible and audible.
They are products of your own mind with its back to the wall.
They indicate that you are close to liberation.
Do not fear them.
No harm can come to you from these hallucinations.
They are your own thoughts in frightening aspect.
They are old friends.
Welcome them. Merge with them. Join them.
Lose yourself in them.
They are yours.
Whatever you see, no matter how strange and terrifying,
Remember above all that it comes from within you.
Hold onto that knowledge.
As soon as you recognize that, you will obtain liberation.
If you do not recognize them,
Torture and punishment will ensue.

But these too are but the radiances of your own intellect.
They are immaterial.
Voidness cannot injure voidness.
None of the peaceful or wrathful visions,
Blood-drinking demons, machines, monsters, or devils,
Exist in reality
Only within your skull.
This will dissipate your fear. Remember it well.

Third Bardo: Preliminary Instructions

O (name), listen well:
You are now entering the Third Bardo.
Before, while experiencing the peaceful and wrathful visions of the
Second Bardo,
You could not recognize them.
Through fear you became unconscious.
Now, as you recover,
Your consciousness rises up,
Like a trout leaping forth out of water,
Striving for its original form.
Your former ego has started to operate again.
Do not struggle to figure things out.
If through weakness you are attracted to action and thinking,
You will have to wander amidst the world of game existence,
And suffer pain.
Relax your restless mind.

O (name), you have been unable to recognize the archetypal forms of the
Second Bardo.
You have come down this far.
Now, if you wish to see the truth,
Your mind must rest without distraction.
There is nothing to do,
Nothing to think.
Float back to the unobscured, primordial, bright, void state of your intellect.
In this way you will obtain liberation.
If you are unable to relax your mind,
Meditate on (name of protective figure)
Meditate on your friends (name)
Think of them with profound love and trust,
As overshadowing the crown of your head.
This is of great importance.
Be not distracted.

O (name),
You may now feel the power to perform miraculous feats,
To perceive and communicate with extrasensory power,
To change shape, size and number,
To traverse space and time instantly.
These feelings come to you naturally,
Not through any merit on your part.
Do not desire them.
Do not attempt to exercise them.
Recognize them as signs that you are in the Third Bardo,
In the period of re-entry into the normal world.

O (name),
If you have not understood the above,
At this moment,
As a result of your own mental set,
Frightening visions may come.
Gusts of wind and icy blasts,
Humming and clicking of the controlling machinery,
Mocking laughter.
You may imagine terror producing remarks:
"Guilty," "stupid," inadequate," "nasty."
Such imagined taunts and paranoid nightmares
Are the residues of selfish, ego-dominated game-playing.
Fear them not.
They are your own mental products.
Remember that you are in the Third Bardo.
You are struggling to re-enter the denser atmosphere of routine game existence.
Let this re-entry be smooth and slow.
Do not attempt to use force of will-power.

O (name),
As you are driven here and there by the ever-moving winds of karma,
Your mind, having no resting place or focus,
Is like a feather tossed about by the wind,
Or like a rider on the horse or breath,
Ceaselessly and involuntarily you will wander about,
Calling in despair for your old ego.
Your mind races along until you are exhausted and miserable.
Do not hold on to thoughts.
Allow the mind to rest in its unmodified state.
Meditate on the oneness of all energy.
Thus you will be free of sorrow, terror, and confusion.

O (name)
You may feel confused and bewildered.
You may be wondering about your sanity.
You may look at your fellow voyagers and friends,
And sense that they cannot understand you.
You may think; "I am dead! What shall I do?,"
And feel great misery,
Just like a fish cast out of water on red-hot embers.
You may wonder whether you will ever return.

Familiar places, relatives, people known to you appear as in a dream,
Or through a glass darkly.
If you are having such experiences,
Thinking will be of no avail.
Do not struggle to explain.
This is the natural result of your own mental program.
Such feelings indicate that you are in the Third Bardo.
Trust your guide,
Trust your companions,
Trust the Compassionate Buddha,
Meditate calmly and without distraction.

O (name),
You may now feel as if you are being oppressed and squeezed,

Like between rocks and boulders,
Or like inside a cage or prison.
Remember:
These are signs that you are trying to force a return to your ego.
There may be a dull, gray light
Suffusing all objects with a murky glow.
These are all signs of the Third Bardo.
Do not struggle to return.
The re-entry will happen by itself.
Recognize where you are.
Recognition will lead to liberation.

Instructions For Re-Entry Visions

O (name),
You have still not understood what is happening
So far you have been searching for your past personality.
Unable to find it, you may begin to feel that you will never be the same again,
That you will come back a changed person.
Saddened by this you will feel self-pity,
You will attempt to find your ego, to regain control.
So thinking, you will wander here and there,
Ceaselessly and distractedly.
Different images of your future self will be seen by you;
The one you are headed for will be seen most clearly.
The special art of these teachings is particularly important at this moment.
Whatever image you see,
Meditate upon it as coming from the Buddha -
That level of existence also exists in the Buddha.
This is an exceedingly profound art.
It will free you from your present confusion.
Meditate upon (name of protective ideal) for as long as possible.
Visualize him as a form produced by a magician,
Then let his image melt away,
Starting with the extremities,
Till nothing remains visible.
Put yourself in a state of Clearness and Voidness;
Abide in that state for a while.
Then meditate again on your protective ideal.
Then again on the Clear Light.
Do this alternately.
Afterwards, allow your own mind also to melt away gradually.
Wherever the air pervades, consciousness pervades.
Wherever consciousness pervades, serene ecstasy pervades.
Abide tranquilly in the uncreated state of serenity.
In that state, paranoid rebirth will be prevented.
Perfect enlightenment will be gained.

Instructions For The All-Determining Influence Of Thought

O (name), you may now experience momentary joy,
Followed by momentary sorrow,
Of great intensity,
Like the stretching and relaxing of a catapult.
You will go through sharp mood swings,
All determined by karma.
Be not in the least attached to the joys nor displeased by the sorrows.
The actions of your friends or companions may evoke anger or shame in you.
If you get angry or depressed,
You will immediately have an experience of hell.
No matter what people are doing,
Make sure that no angry thought can arise.
Meditate upon love for them.
Even at this late stage of the session
You are only one second away from a life-changing joyous discovery.
Remember that each of your companions is Buddha within.
You mind in its present state having no focus or integrating force,
Being light and continuously moving,
Whatever thought occurs to you,
Positive or negative,
Will wield great power.
You are extremely suggestible
Therefore think not of selfish things.
Recall your preparation for the session.
Show pure affection and humble faith.
Through hearing these words,
Recollection will come.
Recollection will be followed by recognition and liberation.

Instructions For Judgment Visions

O (name), if you are experiencing a vision of judgment and guilt,
Listen carefully:
That you are suffering like this
Is the result of your own mental set.
Your karma.
No one is doing anything to you.
There is nothing to do.
Your own mind is creating the problem.
Accordingly float into meditation.
Remember your former beliefs.
Remember the teachings of this manual.
Remember the friendly presence of you companions.
If you do not know how to meditate
Concentrate on any single object or sensation.
Hold this (hand the wanderer an object),
Concentrate on the reality of this,
Recognize the illusory nature of existence and phenomena.
This moment is of great importance.
If you are distracted now it will take you a long time to get out of the quagmire of misery.
Up till now the Bardo experiences have come to you and you have not recognized them.

You have been distracted.
On this account you have experienced fear and terror.
Even though unsuccessful thus far
You may recognize and obtain liberation here.
Your session can still become ecstatic and revelatory.
If you do not know how to meditate, remember (person's ideal).
Remember your companions
Remember this manual.
Think of all these fears and terrifying apparitions as being your own ideal,
Or as the compassionate one.
They are divine tests.
Remember your guide.
Repeat the names over and over.
Even though you fall,
You will not be hurt.

Instructions For Sexual Visions

O (name),
At this time you may see visions of mating couples.
You are convinced that an orgy is about to take place.
Desire and anticipation seize you,
You wonder what sexual performance is expected of you.
When these visions occur,
Remember to withhold yourself from action or attachment.
Humbly exercise your faith.
Float with the stream.
Trust the process with great fervency.
Meditation and trust in the unity of life are the keys.
If you attempt to enter into your old personality because you are attracted or repulsed,
If you try to join the orgy you are hallucinating,
You will be reborn on an animal level.
You will experience possessive desire and jealousy,
You will suffer stupidity and misery.
If you wish to avoid these miseries
Listen and recognize.
Reject the feelings of attraction or repulsion.
Remember the downward pull opposing enlightenment is strong in you.
Meditate upon unity with your fellow voyagers.
Abandon jealousy,
Be neither attracted nor repulsed by your sexual hallucinations.
If you are you will wander in misery a long time.
Repeat these words to yourself.
And meditate on them.

Four Methods of Preventing Re-entry

First Method: Meditation on the Buddha

O (name), tranquilly meditate upon your protective figure (name).
He is like the reflecting of the moon in water.
He is apparent yet non-existent.
Like illusion produced by magic.
If you have no special protective figure,

Meditate upon the Buddha or upon me.
With this in mind meditate tranquilly.
Then causing the visualized form of your protective ideal
To melt away from the extremities,
Meditate, without any thought-forming, upon the Void Clear Light.
This is a very profound art.
By virtue of it rebirth is postponed.
A more illuminated future is assured.

Second Method: Meditation on Good Games

(Name), You are now wandering in the Third Bardo.
As a sign of this, look into a mirror and you will not see your usual self
(show the wanderer a mirror).
At this time you must form a single, firm resolve in your mind.
This is very important.
It is like directing the course of a horse by the use of the reins.
Whatever you desire will come to pass.
Think not of evil actions which might turn the course of your mind.
Remember your spiritual relationship with me,
Or with anyone from whom you have received teaching.
Persevere with good games.
This is essential.
Be not distracted.
Here lies the boundary line between going up or down.
If you give way to indecision for even a second,
You will have to suffer misery for a long, long time,
Trapped in your old habits and games.
This is the moment.
Hold fast to one single purpose.
Remember good games.
Resolve to act according to your highest insight.
This is a time when earnestness and pure love are necessary.
Abandon jealousy.
Meditate upon laughter and trust.
Bear this well at heart.

Third Method: Meditation on Illusion

If still going down and not liberated,
Meditate as follows:
The sexual activities, the manipulation machinery, the mocking laughter,
dashing sounds and terrifying apparitions,
Indeed all phenomena
Are in their nature, illusions.
However they may appear, in truth they are unreal and fake.
They are like dreams and apparitions,
Non-permanent, non-fixed.
What advantage is there in being attached to them,
Or being afraid of them?
All these are hallucinations of the mind.
The mind itself does not exist,
Therefore why should they?
Only through taking these illusions for real will you wander around in
this confused existence.

All these are like dreams,
Like echoes,
Like cities of clouds,
Like mirages,
Like mirrored forms,
Like phantasmagoria,
The moon seen in water.
Not real even for a moment.
By holding one-pointedly to that train of thought.
The belief that they are real is dissipated,
And liberation is attained.

Fourth Method: Meditation on the Void

"All substances are part of my own consciousness.
This consciousness is vacuous, unborn, and unceasing."
Thus meditating,
Allow the mind to rest in the uncreated state.
Like the pouring of water into water,
The mind should be allowed its own easy mental posture
In its natural, unmodified condition, clear and vibrant.
By maintaining this relaxed, uncreated state of mind
Rebirth into routine game-reality is sure to be prevented.
Meditate on this until you are certainly free.

Instructions For Choosing the Post-Session Personality

(Name), Listen:
It is almost time to return.
Make the selection of your future personality according to the best teaching.
Listen well:
The signs and characteristics of the level of existence to come
Will appear to you in premonitory visions.
Recognize them.
When you find that you have to return to reality,
Try to follow the pleasant delightful visions.
Avoid the dark unpleasant ones.
If you return in panic, a fearful state will follow,
If you strive to escape dark, gloomy scenes, an unhappy state will follow,
If you return in radiance, a happy state will follow.
Your mental state now will affect your subsequent level of being.
Whatever you choose,
Choose impartially,
Without attraction or repulsion.
Enter into game-existence with good grace.
Voluntarily and freely.
Remain calm.
Remember the teachings.

The Secret Chief Revealed

by

Myron J. Stolaroff

This Book is dedicated to the memory of Leo, with the fervent hope that the revelation of his work will help bring understanding and sanity to a confused world. May it pave the way for others to reap the benefits he worked so hard to establish.

REVISED EDITION WITH NEW TEXT AND PHOTOS
THE SECRET CHIEF REVEALED
Conversations with Leo Zeff, pioneer in the underground psychedelic therapy movement.
BY MYRON J. STOLAROFF

Table of Contents:

- **Acknowledgments**
- **Introduction to the Second Edition**
- **Prologue**
- **Tribute to Jacob**
- **Foreword**
- **Introduction**
- **Early Beginnings**
- **Selection and Preparation**
  - Selecting the Client
  - Clients with Previous Psychedelic Experience
  - Clients in Therapy
  - Security Problems
  - Preparation
  - Photographs
- **The Individual Trip**
- **The Group Trip**
- **Materials and Doses**
  - Different Kinds of Trips
  - Dose Levels
- **Outcomes**
- **Finale**
- **Epilogue**
  - The Last Trip: Peaceful Closure for Jacobs
- **More Photos**
- **Appendix I**
  - Personal Accounts
    - *Robert*
    - *Susan*
    - *Dick*
    - *Carol*
    - *Sally*
- **Appendix II: New to the Second Edition**
  - Tributes to Leo Zeff
    - *Sara Zeff*
    - *Henry Zeff*
    - *"Andrew"*
    - *"Katherine"*
    - *"Rachel"*
    - *"Julia"*
    - *"Laura"*
- **Appendix III: Resources**
  - Evaluating the Scientific Literature
    - *Books*
    - *Online Resources*
    - *Print Resources*
    - *Bibliographies*
  - By the Same Author
  - About the Publisher: The Multidisciplinary Association for Psychedelic Studies (MAPS)
    - *Supporting the MAPS Mission*
    - *Ordering Information*

This book is dedicated
to the memory of Leo,
with the fervent hope
that the revelation
of his work
will help bring
understanding and sanity
to a confused world.
May it pave the way
for others to reap the benefits
he worked so hard
to establish.

Acknowledgments

I wish to express my thanks to a number of persons who helped to make this book possible.

First, I wish to thank Leo, wherever he may be, for his devoted interest, skill and determination in carrying out this very important work under stressful conditions, guided by his faith and confidence in the value of what he was doing. My wife Jean and I are most grateful for the patience and care that he took to communicate to us his knowledge and experience.

I am also grateful to those who participated in Leo's program, making this work possible, and particularly to those who shared in detail the experiences that they underwent and the results that followed. I also thank Leo's family and supporters who aided him in carrying out his work.

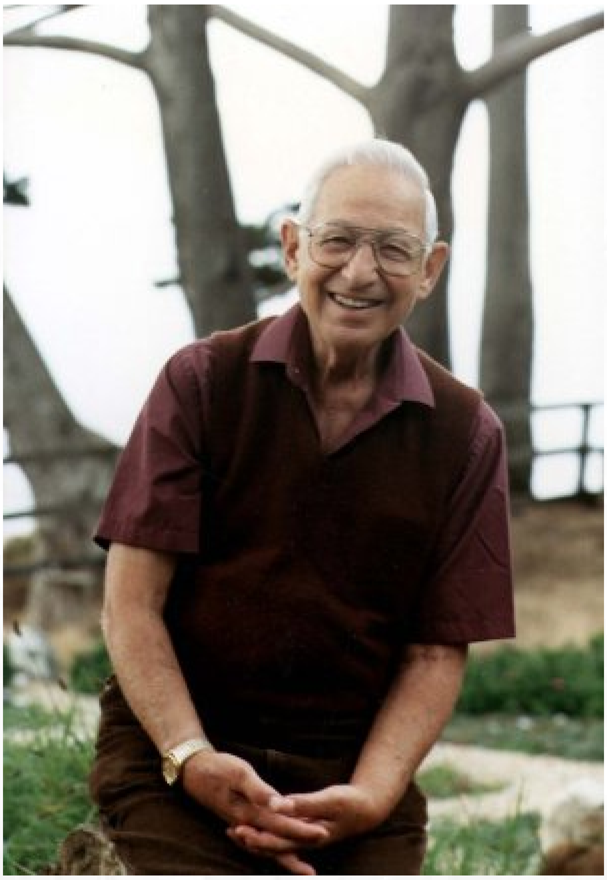
I wish to thank Ann and Sasha Shulgin for pointing out to me the importance of getting Jacob's efforts recorded.

My thanks to Terence McKenna for permission to use his title for this book.

I am extremely indebted to Rick Doblin, Sylvia Thyssen, Brandy Doyle and MAPS for their assistance in the editing and completion of the manuscript, and for taking the steps to have the manuscript published.

I wish to thank my wife Jean for her assistance and loving support throughout all stages of this project, from the initial interviews to the completion of the final manuscript.

Introduction to the Second Edition



THE SECRET CHIEF was published seven years ago, and has now been sold out. Reprinting a new edition provides the opportunity to make some fresh observations, as well as report new progress in the utilization of psychedelic substances. Moreover, the passage of time permits a new development: The Secret Chief no longer needs to be kept secret!

While doing his important work, which our government held to be illegal, Leo lived constantly under the possibility of being discovered and prosecuted as a criminal. Many of those close to Leo who supported his work also lived under the threat of exposure. Even family members feared harassment or investigation. Leo died over seventeen years ago, and the threat to his supporters and companions has evaporated. His family members no longer object to the revealing of his name, and share in the belief that it is time for Leo to receive the acknowledgement he deserves. So we are pleased to present Leo Zeff, Ph.D., the Secret Chief! In this edition, we include photographs of Leo and new accounts written by his son and daughter, as well as new reports taken from interviews with his clients.

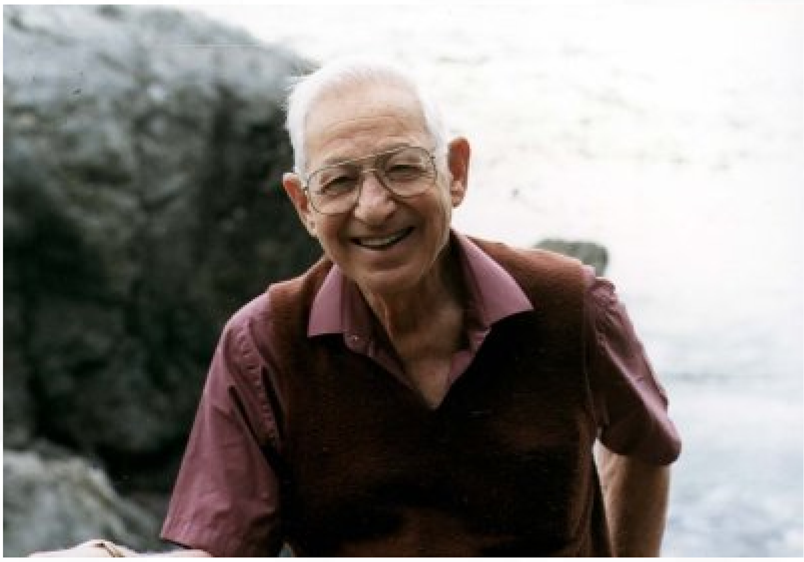
Since the last edition, we have new reasons to hope that the healing techniques Leo pioneered may reach more people. Most promising is the action of the FDA in approving three projects investigating the efficacy of psychedelics as tools for therapy, the first such action in over thirty years. In addition, a number of new, informative books help clear up widespread misunderstanding of the nature and potential of psychedelics.

It has now been 24 years since my wife Jean and I interviewed Leo. What a marvelous experience this was for the both of us! Leo was a remarkable friend, full of life and wisdom and good cheer. It was a true joy to spend many hours with him as he reviewed his work with us. Turning my attention to once again consider his contribution, I feel a deep emptiness in his absence. And yet as I look over what he shared, I cannot help but be immensely grateful for his outstanding contribution.

Still, I am saddened at how a most priceless gift, the psychedelic substances, especially in the hands of Leo and others like him, has been completely denigrated by our government. The enormous potential for healing, for self-discovery, and for communion with the Divine has been prohibited. Those who would pursue such valuable goals can do so only by becoming criminals, as our current laws forbid possession of such substances.

But there is hope. There is a deepening spirituality growing in our nation, and spirituality is a powerful aid to healing. Many extremely worthwhile books are appearing. Some of these pertaining specifically to how psychedelics can help have been added to the "Resources" section at the end of this book. And as mentioned above, the FDA has approved three projects authorizing research with psychedelic substances to evaluate their effectiveness for therapy. One project involves the application of psilocybin in the treatment of Obsessive Compulsive Disorder. Another is employing MDMA in the treatment of Post-traumatic Stress Disorder (PTSD), and a third employs psilocybin administered to advanced cancer patients to relieve anxiety, pain and fear of death. These projects have evolved as a result of anecdotal evidence from underground therapists and users, as well as from previous psychedelic research from thirty years ago. Successful outcomes from these three projects could well open the door to more extensive research.

In the meantime, it would be most helpful if government officials and the public were better informed of the remarkable potential that psychedelics hold for healing, learning, self-development, and authentic spiritual understanding. In general, the DEA and government agencies have feared widespread abuse and damage from such substances. It is true that uninformed or misdirected use of psychedelics can be harmful. The government must certainly take some responsibility for this situation, as criminalizing these substances has prevented important knowledge for harm reduction and beneficial uses to be made available.



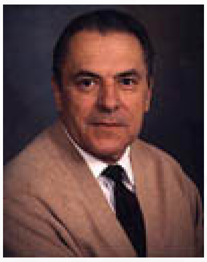
However, for a realistic evaluation of the risks, a number of issues should be taken into account:

1. There are large numbers of users who have learned to use psychedelics properly for their own personal gain, encompassing the range from increased enjoyment or improved functioning to the heights of spiritual development. Many knowledgeable therapists are willing to break the law rather than withhold valuable treatments with these substances from their clients.
2. A minor percent of the population are at risk of developing unhealthy relationships with psychedelics due to personality disorders or other pre-existing psychological conditions. They are often incapable of comprehending the consequences of their actions, including abusing drugs. This minority will always be a problem until we devise better ways to care for them.
3. A fairly large percent of young people live in painful circumstances, in poverty-stricken, abusive, or neglectful families. For an illustration of the drastic effects that lack of intimacy can produce, look at the work of Rene Spitz on the Internet at http://www.hofmann.org/papers/spitz/index.html. The unhappiness of such youngsters lead them to explore almost any avenue that will provide them with a period of enjoyment, regardless of the circumstances or aftermath. Prohibition, however, will not solve the problems faced by these young people. In fact, legalization would make vital information more available, and knowledgeable guides would begin to appear, which in time would reduce misuse.
4. The use of psychedelics is self-regulating in most cases. Their true purpose is to enhance growth and interior development. Used only for pleasure, or abused, the Inner Self is thwarted, which leads to unpleasant experiences and depression. Though everyone who pursues the use of psychedelics for personal growth must be prepared for the "dark night of the soul" experiences, those who seek only entertainment will lose interest in these substances. A good example comes from the book The Pursuit

> of Ecstasy, by Jerome Beck and Marsha Rosenbaum, which reports on a study funded by the National Institute of Drug Abuse (NIDA). "Chapter 5 - Limits to Use: Why People Moderate or Quit Ecstasy," covers a number of factors why people reduce or drop their use of Ecstasy (MDMA) over time, based on a large sample of interviews conducted with a broad spectrum of users.

It must be recognized that despite the action of our government to make psychedelic substances illegal, huge numbers of people have found psychedelics so useful that they are willing to break the law in order to use them. It is hoped that such users can obtain valuable information from this book that will reduce abuse and promote true healing, growth and wisdom. The combination of successful research results and the growth in public recognition of the vital role of psychedelics in healing and personal development, should ultimately restore these enormously valuable tools to our society. Then the dedicated pioneering work of Leo Zeff will be fully recognized and appreciated.

Prologue



Stanislav Grof

After the publication of the first clinical paper on LSD by Walter A. Stoll in 1947, Albert Hofmann's serendipitous discovery of the psychedelic effects of LSD became practically an overnight sensation in the world of science. Never before had a single substance held so much promise in such a wide variety of fields of interest.

For neuropharmacologists and neurophysiologists, the discovery of LSD meant the beginning of a golden era of research that could solve many puzzles concerning the intricate biochemical interactions underlying the functioning of the brain.

Experimental psychiatrists saw this substance as a unique means for creating a laboratory model for naturally occurring psychoses, particularly schizophrenia. They hoped that it could provide unparalleled insights into the nature of these mysterious disorders and open new avenues for their treatment.

LSD was also highly recommended as a unique teaching device that would make it possible for clinical psychiatrists and psychologists to spend a few hours in the world of their patients and as a result of it to understand them better, be able to communicate with them more effectively, and improve their ability to help them.

Early experiments with LSD revealed its unique potential as a powerful tool offering the possibility of deepening and accelerating the psychotherapeutic process, as well as extending the range of applicability of psychotherapy to categories of patients that previously had been difficult to reach such as alcoholics, narcotic drug addicts, and criminal recidivists.

Particularly valuable and promising were the early efforts to use LSD psychotherapy with terminal cancer patients. These studies showed that LSD was able to relieve severe pain, often even in those patients who had not responded to medication with narcotics. In a large percentage of these patients, it was also possible to alleviate or even eliminate the fear of death, increase the quality of their lives during the remaining days, and positively transform the experience of dying. For the historians and critics of art, the LSD experiments provided extraordinary new insights into the psychology and psychopathology of art, particularly various modern movements as well as paintings and sculptures of native cultures.

The spiritual experiences frequently observed in LSD sessions offered a radically new understanding of a wide variety of phenomena from the world of religion, including shamanism, the rites of passage, the ancient mysteries of death and rebirth, the Eastern spiritual philosophies, and the mystical traditions of the world.

LSD research seemed to be well on its way to fulfilling all the above promises and expectations when it was suddenly interrupted by unsupervised mass experimentation of the young generation and the ensuing repressive measures of a legal, administrative, and political nature. However, the problems associated with this development, blown out of proportion by sensation-hunting journalists, were not the only reason why LSD and other psychedelics were rejected by the Euro-American culture. An important contributing factor was also the attitude of technologized societies toward non-ordinary states of consciousness.

All ancient and pre-industrial societies held these states in high esteem and they devoted much time and energy trying to develop safe and effective ways of inducing them. Members of these social groups had the opportunity to repeatedly experience non-ordinary states in a variety of sacred and secular contexts. Because of their capacity to provide experiential access to the numinous dimensions of existence and to the world of archetypal realms and beings, non-ordinary states represented the main vehicle of the ritual and spiritual life of the pre-industrial era.

They also played an essential role in the diagnosing and healing of various disorders and were used for cultivation of intuition and extrasensory perception. By comparison, the industrial civilization has pathologized non-ordinary states, developed effective means of suppressing them when they occur spontaneously, and has rejected or even outlawed the contexts and tools that can facilitate them.

Because of the resulting naivete and ignorance concerning non-ordinary states, Western culture was unprepared to accept and incorporate the extraordinary mind-altering properties and power of psychedelics. The sudden invasion of the Dionysian elements from the depths of the unconscious and the heights of the superconscious was too threatening for the Puritanical values of our society. In addition, the irrational and transrational nature of psychedelic experiences seriously challenged the very foundations of the world-view of Western materialistic science.

The existence and nature of these experiences could not be explained in the context of the mainstream theories and seriously undermined the metaphysical assumptions on which Western culture is built. For most psychiatrists and psychologists, psychotherapy meant disciplined discussions or free-associating on the couch.

The intense emotions and dramatic physical manifestations in psychedelic sessions appeared to them to be too close to what they were used to considering to be psychopathology. It was hard for them to imagine that such states could be healing and transformative and they did not trust the reports about the extraordinary power of psychedelic psychotherapy. In addition, many of the phenomena occurring in psychedelic sessions could not be understood within the context of theories dominating academic thinking. The possibilities of reliving birth or episodes from embryonal life, obtaining accurate information from the collective unconscious, experiencing archetypal realities and karmic memories, or perceiving remote events in out-of-body states, were simply too fantastic to be believable for an average professional.

Yet those of us who had the chance to work with psychedelics and were willing to radically change our theoretical understanding of the psyche and practical strategy of therapy were able to see and appreciate the enormous potential of psychedelics, both as therapeutic tools and as substances of extraordinary heuristic value.

In one of my early books, I suggested that the potential significance of LSD and other psychedelics for psychiatry and psychology was comparable to the value the microscope has for biology and medicine or the telescope has for astronomy. My later experience with psychedelics only confirmed this initial impression. These substances function as unspecific amplifiers that increase the energetic niveau in the psyche and make the deep unconscious dynamics available for conscious processing. This unique property of psychedelics makes it possible to study psychological undercurrents that govern our experiences and behaviors to a depth that cannot be matched by any other methods and tools available in modern mainstream science. In addition, psychedelics offer unique opportunities for healing of emotional and psychosomatic disorders, for positive personality transformation, and consciousness evolution.

Naturally, tools of this power carry with them greater potential risks than more conservative and far less effective tools currently accepted and used by mainstream psychiatry, such as verbal psychotherapy or tranquilizing medication. However, past research has shown that these risks can be minimized through responsible use and careful control of the set and setting. The legal and administrative sanctions against psychedelics did not deter lay experimentation, but they did terminate all legitimate scientific research of these substances.

For those of us who had the privilege to explore the extraordinary potential of psychedelics, this was a tragic loss for psychiatry, psychology, and psychotherapy. These unfortunate developments wasted what was probably the single most important opportunity in the history of these disciplines. Had it been possible to avoid the unnecessary mass hysteria and continue responsible research of psychedelics, they could have become a tool that would make it possible to radically revise the theory and practice of psychiatry.

This research would have brought a new understanding of the psyche and of consciousness that could become an integral part of a comprehensive new scientific paradigm of the twenty-first century. Most of the LSD researchers grudgingly accepted the legal and political sanctions against psychedelics and reluctantly returned to mainstream therapeutic practices. A few attempted to develop non-drug methods for inducing non-ordinary states of consciousness with the experiential spectrum and healing potential comparable to psychedelics. And then there were those who, like Jacob, the "Secret Chief," refused to accept legal sanctions that they considered irrational, unjustified, or even unconstitutional.

These researchers saw the extraordinary benefits that LSD therapy offered to their clients and decided not to sacrifice the well-being of these people to scientifically unsubstantiated legislation. In addition to the therapeutic value of psychedelics, they were also aware of the entheogenic potential of these substances - their capacity to induce profound spiritual experiences. For this reason, they understood their work with LSD to be not only therapeutic practice, but also religious activity in the best sense of the word. From this perspective, the legal sanctions against psychedelics appeared to be not only unfounded and misguided, but also represented a serious infringement of religious freedom.

Jacob painfully weighed the pros and cons and made the decision to challenge the law, continue his work with psychedelics, and assume personal responsibility for his activity. He has already passed the judgment of his "family," the friends and clients whose lives he has profoundly changed. They remember him with great love and gratitude. It remains to be seen how he will be judged by history. It is certainly wise to obey the laws if our primary concern is personal safety and comfort. However, it often happens that in retrospect, history places higher value on those individuals who violated questionable laws of their time because of foresight and high moral principles than those who had issued them for wrong reasons.

Tribute to Jacob

Ann Shulgin

I first met Jacob, the man who is the subject of *The Secret Chief* - I called him Adam Fisher in *PIHKAL* - in the early 1980s, shortly after I met Sasha Shulgin. One of the great stories I heard from Sasha was about this wonderful psychologist who had - for many years - been guiding certain carefully selected clients through psychedelic sessions. In the early 1970s, this elderly gentleman decided to retire from his regular clinical practice. A chemist friend of Sasha's had, at that time, just rediscovered a drug which had been sitting on a German chemical company shelf, so to speak, since its synthesis in 1912. She had tried it and reported interesting effects to Sasha, who went into his own lab and made the drug, 3,4-methylenedioxy-methamphetamine - known as MDMA - and tried the result in himself. He called Jacob and told him there was a new drug that might be of interest to him, and shortly afterwards, took it over to Jacob's little apartment.

The rest, as the saying goes, is history. Jacob postponed his retirement, completely enraptured by the effects of MDMA on himself and his patients. Over the next few years, he traveled around the country, quietly training groups of therapists in the use of MDMA in psychotherapy. He occasionally went to Europe to continue this work among European psychologists and psychiatrists. He always insisted that any therapist who intended to make use of this magic drug had to try it in himself first. That has been the rule ever since, whenever healers wish to make use of either MDMA - which is not a psychedelic drug - or any of the true psychedelics in their therapy. The therapists must know the effects of any such drugs in themselves, before giving them to anyone else.

At his memorial, I asked one of his oldest friends whether she had any idea as to how many people Jacob might have initiated over the years in the use of psychedelics, and she replied, "Oh, I would guess about four thousand, give or take a few." Rather extraordinary, for a man in his seventies!

Jacob himself, when I knew him, was everybody's idea of what a grandfather should be. His thinning hair was silvery white. He had a slightly rounded face, and the years had etched into it indelible proof of kindness and humor. One look, and you would instantly trust him to listen and empathize. He was quite capable of anger and stern judgment, but these were reserved for very few people. Malice disturbed him - as it does most of us - but the only time I heard him speak with absolute disgust was when he explained the meaning of what he called the "bear-trapper." That was his term for borderline personality. I suspect he'd been badly burned by at least one, in his career as a clinical psychologist.

When I was very young, first hearing and reading about psychology, the worst possible diagnosis used to be something called "inadequate personality." Many of us would have preferred to be diagnosed as paranoid schizophrenic! At least, there could be a smidgen of tragic drama attached to paranoia and/or schizophrenia, but to be thought of as an "inadequate personality?" Total horror. These days, the most dreaded diagnosis (speaking of non-violent, non-psychotic patients) is "borderline," and Jacob used the term, "bear-trapper," because, as he explained it, such patients usually try to draw their therapists into their own world, instead of using whatever help the therapist offers. Their goal, as he saw it, is not to gain health, but to seduce the therapist into keeping them company in their state of sickness. They are highly manipulative and, if confronted directly, can become vengeful and destructive. When I first met Jacob, I had not yet begun to do my own work as a psychedelic therapist, and didn't fully understand what he meant by "bear-trapper." I believe that the official definition of such a hapless soul is something like, "Help-refusing complainer," which covers a lot of ground in a very few words. Not too many years later, I began learning how to do therapy with MDMA and psychedelics, and ran into two examples of what Jacob had warned me about. As a result, I finally understood my dear friend's allergy to such people, although I was never sufficiently burned, myself, to develop the kind of anger Jacob had expressed towards them.

Jacob was not a brilliant genius, but he was one of the people from whom I learned most about what is called "wisdom," because that is what he had. He could take a situation which would ordinarily cause high frustration or anxiety in anybody else, and turn it into a wonderfully palatable spiritual lesson, seasoned with great humor and joy.

When you asked Jacob a meaningful question, his answer tended to give you the maximum amount of useful information in the least number of words. And he had learned not to be defensive about making mistakes. In fact, I never saw Jacob being defensive about anything; he was at peace with himself and comfortable with who he was, which is certainly one of the definitions of a good healer.

I described, in PIHKAL, Jacob's role in helping me through a strange and extraordinary week of consciousness change which happened many years ago. It was his words, "What you're going through is a process. All you have to do is not get in its way," that gave me my bearings and enabled me to regard the entire experience as a chance to learn and grow, which is exactly what it became.

The strangest thing about Jacob, for many of us, was the fact that, as a young man, he had been in the United States Army and loved it. He was amused by the bewilderment of so many of his friends, who couldn't quite understand how a deeply committed psychedelic guide and therapist could regard past duty in the military as a productive and enjoyable experience. Most of us eventually realized that the problem was in our own prejudices and projections, not in Jacob's validation of both worlds. I asked him once whether he thought there was any hope for survival of our species, considering the apparent determination of so many of us to poison our environment and destroy each other. He turned to me, smiling, "I think we'll make it. Humanity has a funny way of turning itself around when it has to. Maybe not all of us will survive, but I have no doubt at all that our species will. It's happened many times before; it will again."

We miss Jacob. That old cliché, "It is a privilege to have known him," is absolutely appropriate, for Sasha and me and for all of his friends. The only thing I can't forgive him for is that he left this plane, this reality that he shared with us, without my knowing in time. I wasn't there, by his bedside, and it still grieves me when I think about it. One of these days, one of these years, I will be able to give him permission - from my heart - to go, but I haven't been able to do it yet.

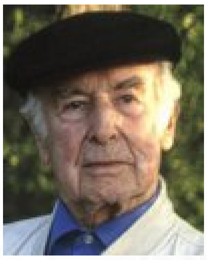
Foreword



Albert Hofmann

Hardly any other science is as conservative and tradition-bound as is medicine. Whenever a new treatment modality or an extraordinary medicine appears, in addition to interested acceptance in specialist circles there is also opposition to the novelty, which is emotional and vehement, in proportion as the innovation is significant and pioneering. Hypnosis may be cited as an example. It was denounced as dangerous charlatanism, and more than a century had to pass before it gained entry into mainstream medicine.

Today a novel group of psychoactive substances, which have come to be known under various designations - hallucinogens, psychotomimetics, psychedelics and recently entheogens - has evoked violent controversy in professional circles and the media. These are substances capable of profoundly affecting human consciousness. This explains the vehemence and the passion which accompany discussions of the 'psychedelics,' as these materials are mostly known today, since we are talking about the veritable inner core of our humanity, our consciousness.

On the other hand, one would imagine that the psychedelics might have gained especially easy entry into medicinal practice, since we are dealing here with active principles of drugs which for millennia have played a meaningful role in archaic cultures and which even today among primigenial peoples find beneficent application in social and medicinal fields. Had we from the outset harked back to these archaic experiences, we would have been able to avoid the misuse and improper use of these extremely potent psychopharmaceuticals, and they would not now be prohibited, but would rather have become valuable medicines in the contemporary pharmacopoeia.

The substances under discussion are above all mescaline, the active agent of a Mexican cactus which the Indians call *péyotl* or peyote; psilocybin, the active principle of the Mexican 'magic mushrooms' *teonanácatl*; and LSD (chemically *Lysergsaure diethylamid* or lysergic acid diethylamide), which is closely related to lysergic acid hydroxyethylamide, the active agent of the ancient Indian 'magic drug' *ololiuhqui*.

All of these drugs are integrated into tribal cultures and employed as 'magic medicines' in a religious-ceremonial context. Their use is in the hands of shamans or shamanesses, male or female priest-doctors, where they manifest a beneficent action. They are esteemed as sacred, and according to Indian belief, their misuse or profanation is punished by the gods with insanity or death. International research with these substances - especially in psychiatry, to investigate their use as pharmacological adjuncts to psychoanalysis and psychotherapy - commenced shortly after the 1943 discovery of LSD, which is by far the most potent representative of the psychedelics. Besides the greatest enthusiasm in response to outstanding results with LSD and other psychedelics, scepticism also manifested itself in conservative circles, particularly those in which any pharmacological intervention in the treatment process was rejected.

This very promising use of psychedelics in psychiatry and psychology came to an untimely end midway through the sixties, when this new class of pharmaceuticals was outlawed, with the complete prohibition of their manufacture, possession and use. Accidents involving psychedelics resulting from frivolous, uncontrolled use in the drug scene were the ostensible reason for this prohibition. The principal reason for the draconian prohibitive measures, however, was the goal of attacking the youth movement, hippies and the like, who opposed the Establishment and the Vietnam War, and whose 'cult-drug' was, above all, LSD.

Medicinal use of the psychedelics was prevented by the official prohibition, and further research in this field was interrupted, while consumption continued in the drug scene. This irrational situation still largely exists today[1]. For therapists, the use of psychedelics became a criminal matter, for which they could face punishment.

One of the probably very few therapists who continued to use psychedelics, accepting the great risk of criminality, was the psychologist here referred to by the alias 'Jacob' and dubbed the 'Secret Chief'[2]. Jacob had obtained mostly excellent results from his specially-developed techniques in the use of psychedelics, and he realized that this therapeutic method should not be withheld from sick people. His ethical obligation as a therapist, to help people, took priority for him over obedience to a dubious official prohibition.

In the illegality of his time it was unthinkable to publish the excellent results of his therapy. It is therefore praiseworthy that today, nine years after his death, a friend has undertaken the task of publishing the details of the therapeutic methodology of this intrepid Ph.D. psychologist. The therapeutic results attained from this method constitute an important argument in the current growing discussion challenging medical circles, whether again to liberate psychedelics for psychotherapeutic practice.

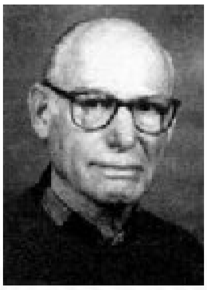
1. On the other hand, some very limited psychedelic research was permitted to begin again in 1990.-Ed.
2. Jacob was nicknamed the "Secret Chief" by Terence McKenna.-Ed.

Introduction



Myron J. Stolaroff

It is rare in life to meet a person so engaging, so warm, so obviously kind that your heart automatically goes out to him at first contact. Jacob was such a person. Completely unpretentious, he was tremendously enthused with life and excited about people.

Jacob died in the spring of 1988 at the age of 76, after an unusual and illustrious career. He was outstanding in his field, and made many significant contributions. Yet because of the unorthodox character of his chosen work, he was little known outside his immediate circle of friends and clients. In fact, I cannot even use his correct name, nor give you the locale of his activities. Yet if he and his work were truly known, the world would recognize that it has lost one of its most able pioneers and a man who has made a very important contribution to the field of psychology. A close and knowledgeable friend, who had the opportunity to understand him better than most, dubbed him the "Secret Chief," which is a most fitting title for this work.

It was in the spring of 1981 when my wife Jean and I met with him to have these conversations. He was already 70 years old, and retired from his very engrossing work. He was a short man, about five feet six inches tall, somewhat stocky, almost white-haired, and hardly ever to be caught without an engaging smile. As soon as you were in his presence you knew that he was your friend, and would do anything he could for you. He was proud of his Jewish heritage, and also proud of his service in the army, where he attained the rank of Lieutenant Colonel.

Jacob was a psychologist, and one of the first to be licensed as a Ph.D. in the state in which he practiced. For many years he conducted a private practice as a Jungian therapist.

Jacob's life changed dramatically in the early 1960s, when he became acquainted with the mind-altering substances LSD and mescaline. These powerful drugs not only led him into a whole new area of self-understanding, but he found them to be enormously effective in helping his clients - so much so that he abandoned conventional therapy to pursue the study and practice of using these new substances.

Jacob made great personal progress, and at the same time learned a good deal about how to use these chemicals effectively. He developed many useful procedures and had a large following of clients wanting to take advantage of this new, powerful means of therapy. In time, Jacob not only was responsible for processing around three thousand individuals, but he shared his experience in this new art with over one hundred therapists. By the time these conversations were held, he was responsible probably more than any other individual alive for introducing individual clients and therapists to the benefits and procedures of effectively using mind-altering substances in personal growth.

My purpose in interviewing Jacob was to become familiar with the practices he had developed. There were many of us who believed that his valuable techniques should be published and made available to other researchers and for posterity. One huge, giant obstacle confronted us: Most such substances had been placed in Schedule I of the Federal government's Controlled Substances Act, making them illegal to possess. So there was considerable risk of exposure in making such information public.

Jacob agreed to transmit the information and have it on record, and we agreed that we would decide later on its disposition. When the information had been reduced to writing, Jacob decided that it was too sensitive to be published, so it was set aside. Now that he is no longer with us, and immune to whatever legal transgressions he may have committed, it becomes possible to tell his story and acknowledge the outstanding pioneering work that he accomplished.

Most of what follows is in Jacob's own words. I have done some editing for the sake of clarity, and have arranged some discussions in more logical progression. Also, appropriate fictitious names and locations have been used with an eye to our repressive drug laws. Many of the very promising substances Jacob worked with are in Schedule I, making it exceedingly difficult to research their beneficial uses[1].

The decision to use Jacob's own words took much pondering on my part. Several who have seen the initial form of this manuscript felt that Jacob's uninhibited language and looseness of expression would turn many potential readers away, and they preferred a more scholarly, professional rendition. But those who knew Jacob will delight in once more experiencing his expressions, fondly recalling past conversations and the images of this dear person they invoke. Such expressions may likely be lost on readers who never knew this man, and who could very well object to the sometimes coarse language.

But this gets to the very heart of some of the misunderstandings about psychedelics. Jacob was a man who brought new life and opportunity to many hundreds of individuals, often in total life-transforming ways. He was dearly loved. This was not because of his elegant expression or professional training. It was because he was blessed with an abundance of heart, the most necessary prerequisite for someone accompanying others into the depths of their very souls. For the unconscious mind is often terribly frightening; we have made much of its contents unconscious because we want nothing to do with it. It takes a strong heart, honesty, and a desire to learn and face one's problems in order to enter the dark areas of our suppressed inner self.

Nothing is more helpful than the presence of a kind, loving, understanding person thoroughly familiar with the dark regions of the mind - a companion who is confident of his ability to help one navigate and resolve those regions that have been an enormous burden in the past, a person who knows the wonder of being free. Whoever understands all of this certainly is not concerned about the person's modes of expression, but is only grateful for the heartfelt support.

And this Jacob expressed in abundance. A person who felt deeply, he understood that expressing such feelings is the most honest way of being oneself. It is not the choice of words, but the ability to feel deeply and genuinely express one's feelings that make one authentic, and which brings people together in true relationship. Since so many of us are afraid of our feelings, the dark side of our unconscious is replete with feelings we do not dare to feel. Once we learn how to find and express them, we can feel the delight of being fully alive by honestly expressing them. Then we deeply appreciate those who function this way.

So in submitting Jacob in his native tongue, I feel that I avoid the disservice of not fully presenting him. I very much hope that the reader, through encountering Jacob's personal expressions, can more readily discern the heart of one of the truly great persons who have lived on this earth. Yes, it's probably true that a man with a Ph.D. in psychology might have learned to speak more correctly, but once you have the privilege of being in this man's presence, who cares?

May you enjoy this introduction to our good friend and psychedelic guide par excellence, Jacob.

Lone Pine, California

1. The Drug Enforcement Administration, which initiated the scheduling of practically all psychoactive materials, claims that placing the substances into Schedule I does not preclude research. While there is a procedure for researching Schedule I materials, in practice for almost three decades, virtually no clinical research was permitted on this class of substances. The control is exercised by the Food and Drug Administration, which must grant an IND or Investigational New Drug exemption to permit research. For Schedule I materials, a protocol must be submitted and approved by the FDA. At the time of these interviews, numerous applications for IND's for psychoactive materials had been turned down. Beginning in 1990, there has been a liberalization of this policy. In 1997, there are several research projects with psychedelic substances that have been approved by the FDA and the DEA.

Early Beginnings

Jacob: What I was hoping was that you would be able to prepare questions - I work better in response to a stimulus rather than just talking out of my head.

Myron: How did you first get into the use of psychedelic agents?

Jacob: I think it was in 1961, something like that. One of my former patients called me and said, "Jacob, I want to see you. I want to talk to you about something." I said, "All right." She said, "I want to tell you about an experience I just had. I can't talk to anyone else about it because I don't think they'd understand it." So I said, "Sure. Come on in."

She came in and sat down and told me that she had recently had an LSD trip. She told me about her experience, and I was fascinated by it. She felt that I was the only one who could understand it because I was Jungian. I had training as a Jungian analyst and I was doing Jungian analysis at that time.

Well, I was just amazed at this experience, just flabbergasted, because, my God, here I'd been working over 30 years in various disciplines and studies and meditations and all that kind of stuff and every now and then getting a glimpse of the truth on an experiential level. Here, this gal comes in and tells me she dropped this minute quantity of material and she had a solid day of nothing but all those beautiful peak experiences that people will get out of it, and tremendous insights and many growth things and all that. I was very surprised. Didn't do anything about it, particularly. I asked her some questions, but I knew that there was nothing that you could even question about it. You just listen to it and get what she's saying. I got a contact high from her, though! (He laughs heartily.)

About three or four months later another person, a man whom I had worked with earlier, called me. He said "Jacob, I've got to talk to you. I've got to see you about something." I said, "Fine, come on in." He came in and he sat down and he told me he had just had an LSD experience. Well, he told me about his experience, and it was every bit as spectacular as the other one that I'd heard from the lady. Then I really got interested. Not only that, I wanted to find out how the hell I could get into something like that!

I decided to look into it. I had some friends here, and they were into it and knew a lot about it. I wanted to get some information about this stuff for myself. One of them had Sandoz's annotated bibliography of every article that had come out that had been printed until then, and he let me read it. There was something like 1,000 different references, all phases of psychedelics and a paragraph digest of many of the articles. I read that through from the beginning to the end and was very, very impressed because of the tremendous potential that was pointed out from the material in terms of the experience that people had from it. It was mostly LSD and psilocybin. All the tremendous great things they said about it and what came out of scientific journals.

There were only two or three references to something bad. Those mostly were because somebody gave it to somebody without telling them what it was or under the wrong circumstances. I believe one of them was when they gave it to a nurse in a hospital while she was on duty. She didn't know what was happening. She freaked out and jumped out the window, down about seven stories, something like that, and killed herself.

Then I really got serious about exploring. One of the first things I did was find out who's doing it. One of the first places I found out who was doing it was a place set up for just this purpose. I found that out because one of their staff came to give a talk to some psychologists. He talked about the LSD. I met him; that's the first time I ever met him. We had a talk, and he got to realize that I had a great interest in it. He's the one that told me about their place. I went down to visit them and he showed me around, told me things, and gave me the idea of the setup.

I found out other people who were working with it at that time. We had a meeting of people who were interested in it and did a lot of talking about its potentials, shared experiences that people had and all of that. Then there were a couple of other places that I went where people knew things about it. In fact I went to a meeting where Aldous Huxley spent an evening with us telling us all about it. He had a place for tripping in Mexico, a health resort. I went down there once for a trip with another therapist and her group.

When I was so interested and fascinated by it someone whom I don't remember any more said, "Jacob, why don't you try it? Find out what it's all about?" I said, "I'd love to, but I don't know where to get it or who to talk to." He said, "What're you talking about? All these people, any one of them, could give you a trip."

I knew someone who was interested in these materials. I was talking to him and asked him if he knew anyone who was willing to give me a trip. He says yes, he knew where I could get a trip and he told me about a fellow who was doing this work. This guy arranged one for me with him and his wife. So I went over there and had a trip. Didn't have much; didn't take much. I get a full trip out of 100 micrograms acid. They gave me the acid, and I took it, and - nice circumstances, very pleasant, secure. Then I start to turn on. I lay down on a kind of divan that they have there and we played some music and as I really started to turn on, they started to turn on.

I remember that the first thing I said was, "Why can't it be like this always?" It was a very deep, emotional trip. He asked me to bring some things along that were important to me, and I brought my Torah. I have my own Torah in its ark. Someplace along the line he was playing Kol Nidre, I think. He laid the Torah across my chest and I immediately went into the lap of God. He and I were One. That was - (feeling strong emotion). I can't remember all the different things. What happened was another thing I said out loud - he copied down what I said out loud - I use tape recordings to catch what people say - I said, "Jacob, if ever again you are frightened you deserve the pain of the fear because you will have forgotten that God is with you and protecting you all the time."

As I was coming down I had some pictures that I brought along - pictures of my family - pictures of my father and my brothers and my mother. The outstanding experience there was, I looked at pictures of my father and my brothers and myself as I was a little boy - and we all were the same person, all of us. There was no difference between us.

I looked at the picture of my mother that I had there and it came alive and I took hold of her hand and we walked through a forest glade or something like that. And I told her - I can cry again, my God - I told her all the different things that I'd never been able to tell her in my life. Just told her what they were! And she listened to them all, she heard them, she did not respond yet we were communicating beautifully. There were other things that happened on the trip, but now I'm going to stop and go to another point.

The space that I was in at the time that I tripped - I was just in the beginning of the late forties - the 50 year crisis that people have going into the second half of life. I see it more as the time when you really get into the spiritual search. I was pretty damned depressed and pretty well ridden with anxieties which are characteristic of that stage. I was dissatisfied with myself, dissatisfied with my work as an analyst. While I was aware of the value of the work I was doing, I was more acutely aware of its limitations. Having the people come in once a week - I never did see people more often than once a week, maybe twice a week if they were in a crisis - and talking and talking and having hit the desert space, the dead space of life where nothing's happening. And listening to them talking and talking, trying to get out of it working with dreams and all that and nothing happening, and realizing God-damn, Jacob, there's nothing you can do except wait until life comes along and gives them a big kick in the ass and they get going again. Nothing's going to happen from me except to be there to listen and to support them.

Well I was in that kind of a space myself, not knowing what to do, where to go. I could only do what I could do; I tried different solutions, but they didn't work. I read books, I read about spiritual things, about God and all that. I got value from it, but it didn't get me out of where I was, actually.

One of the things on the trip that occurred to me was, Jacob, this is the answer you've been looking for! If something like this can do this to you, then - well, I don't know if I filled it out other than saying well, my God, this can jar people loose, this can break people through, this can do all kinds of things. Look what it's doing for you.

I decided then to explore it much more thoroughly. I wanted more trips, to have more experience, to develop it more. I had to find people who had material, that I could get them to sit with me. I remember being with - oh, he was a physician - he was exploring the materials, and I wanted to try grass. He said all right, come by the house here, and I'll have some grass for you and we'll turn on. Well, I was smoking cigarettes in those days. He laid out some joints for me and told me how to inhale it and hold it and all that and so I started to smoke the grass. I smoked it like cigarettes. I inhaled a big drag, held it in my lungs as long as I could and blew it out, then inhaled another one. I did that through two and a half joints, and this was good stuff.

What happened was I really freaked out. I got paranoid as hell! I was lying down on the couch there after I had finished a piece. The agony of the damned went on and on and on such as can happen. Paranoid as hell! Scared to death of everything. If the phone rang I knew it was the police coming in and there was nothing I could do but just give myself up and all that kind of stuff. It was torture! It was a horrible bummer; I had never had a bummer like that in my life until then.

Myron: Were you alone?

Jacob: No, he was there. Some place, about two to three years into it, he came by and put a dish down by me and I picked up my eye and looked at it. I didn't know what it was. I picked up my eye a couple of years later and looked at it and it was some ice cream, with a spoon. He said, "Have some ice cream, Jacob; go ahead."

I picked it up and I took a spoonful of ice cream. I never tasted such ambrosia in my life! It was the exact opposite experience of what I was having. Heavenly! I ate and ate and ate for I don't know how many years. Every bite was so beautiful! Finally I licked the spoon and I licked the bowl clean. I put i t back down, laid back on the couch, and went right back into the bummer!

It took quite a while for me to come down from it, and I did. That was my second trip. I had some other trips that were very nice. I can't remember specifically now. I did have mescaline; that was good, very spiritual, very nice. I took acid some more. Two very interesting and important experiences I had. One was with an experienced psychiatrist, let's call him Louis. Let me see if I can remember what the hell I had then. I think it was an acid trip. I remember I was smoking at that time, I was smoking a pack and a half a day, which is a lot of cigarettes. I was having problems at home with my wife, and was pretty unhappy then in my home life. On this trip I was talking - I was coming down from it, somewhat - and I was talking to Louis about things. He had asked me questions to get me to talk, and I was talking about Jane. I was saying something about the problems that I was having with her. I couldn't talk to her, I couldn't relate to her, she was very frightened about anything that I was doing and very paranoid about me. Very jealous, absolutely no reason of any kind at all. I used to have migraines in the early days, but more than anything else what bothered me the most was the fact that she smoked, constantly. And I'm allergic to cigarette smoke. I was telling him that. I was telling Louis, "See. I can't stand cigarette smoke." Louis looks at me and I'm sitting there with a cigarette in my hand. I say, "I'm allergic to smoke, to cigarette smoke."

He says, "You're allergic to smoke?"

I said, "Yes."

He looks at the cigarette and looks at me, and looks at the cigarette, and I look at the cigarette, too. I'm still pretty stoned. I looked and looked and looked for a *long, long, time*, I looked at that cigarette. Hours, just looked at it. Many things were going through my mind. Louis says to me, "Well, if you're allergic to cigarettes, are you going to stop smoking?"

After a long pause, I don't know what time it was, but I responded. I said, "That's the wrong question, Louis. The question is not, am I going to quit, the question is, *have* I quit?" I watched that cigarette burn down to the cork tip in my fingers, and I stuffed it out. And I've never smoked a cigarette since then. I was never *able* to. I had tried to stop many times, you know how you try to stop. I've never smoked a cigarette since then.

There's another incident, too, an experience in my home that I had that was a very important one. I've had migraines all my life. The earliest memory I have of myself is lying on the front porch of my house at home while they're paving the street and the tar was there as they were paving the street and bricks as they used in those days and the tar smell was making my head ache so bad. That's the earliest experience I had. About three, maybe four years old. The headaches were extremely severe and painful. Pretty bad constantly.

One day I was tripping in a group trip. I was having an ibogaine trip. Do you know ibogaine? It's a fantastic medicine, really. I think I mentioned that we use the word medicine rather than drugs.

You get the answers to all your questions on this trip, on the ibogaine trip. Everything is clearly stated, any questions you have. You go into the trip with questions if you want to. You ask the question but you don't try to answer it. The answer comes to you. This time I decided to ask Mr. Ibogaine - we call him, the person from whom you get the answer, Mr. Ibogaine. Anyway, my question was, what is this with these headaches that I have, that I suffer from? That's all. I was really turned on and deep in a trip and the question occurred to me. Okay, ask it. "What is it with these headaches?"

The answer came. I've had a number of ibogaine trips and the answer always comes. You may not recognize it for what it is, it may be very ambiguous or somewhat like that, but you've got the answer for sure, you'd better hang onto it. The answer came back and said, "You're going to die." I looked, and I said, "What?" That's what it said. I know it said it. I looked around it, and it said I'm going to die.

You don't get frightened with an experience like that. You just take whatever's handed to you and look at it, handle it. So I looked at it, and I looked at it and I said, "Jesus Christ, what does that mean, I'm going to die? Well it means you're going to die, that's all it means." Die when? Of course I knew I'm going to die some day. I know that, that's nothing new. This isn't the kind of "You're going to die" that Mr. Ibogaine was saying.

I said, "Well, gee, this is something between me and Mr. Ibogaine. It is not something that I can tell anybody about." On the report of my trip - we all gathered the next morning and told what happened on our trip - on the report of my trip, I could not say anything to them about Mr. Ibogaine's saying I'm going to die, since that would scare the hell out of everybody. They wouldn't know how to take it.

I didn't know how to take it. I never did know. I kept reflecting on it for quite some time. And it was about a month later. The only relief I could ever get for migraine was codeine. And I took one helluva lot of codeine. I was certainly habituated, but not addicted because there were times I wanted to quit taking it, and I decided I was going to quit. I did quit; I quit for weeks, and I could do it! Without too much trouble. And my migraines would be easier on me even then. But then I'd get back on it again. I was taking as many as four to eight half-grain tablets of codeine every day, so that I could function without the pain.

A month after this trip I took another trip. I don't remember what the material was. It wasn't ibogaine. I was with somebody, I can't remember who it was, I don't even remember if it was a man or a woman. I took something, I think it was acid, and had my trip. As I was coming down from the trip, as most of the people liked to do and as I always wanted to do, I walked down to the water. I walked along the water, which was a very important place for me. That's where I had my greatest conversations with God. That was really a very important thing to me. I remember walking along, talking to God, and coming back up to the house. As I was coming up the hill something flashed in my mind, something that was a result of the space I was in from the trip. What flashed in my mind was a phrase.

I know that when lots of times you take an ibogaine trip you get something that's enigmatic, you don't know what it is, and later on you'll get something that fills it in. Completes the sentence is really what it does. It turns out that "You're going to die," was part of a sentence. The second part of the sentence flashed into my mind. "Unless you stop taking codeine."

I rolled that one around and rolled it around and rolled it around and looked at it. God-damn! How can I function, unless I take codeine? I just played around with it a lot. Maybe I haven't got the right message, or something like that. Then I said, "No, Jacob, don't fuck around with this stuff. You know the answer. You take it. You got the right message. Take it, just as you got it. *I'm going to die unless I stop taking codeine*. Okay, I got the message. That's the truth, I know that's the truth. So, what am I going to do about it? Am I going to quit taking codeine? It doesn't bother me to die. I'm going to die some day. But - I'm not ready yet. I don't want to, right now. Am I going to quit taking codeine?"

And it flashed in my mind the answer, this statement. "Jacob, that's the wrong question. The question is not 'Are you going to quit taking codeine?' The question is, 'Have you quit taking codeine?'" The same thing that happened with the cigarettes. And I knew the answer. *Right then and there I knew the answer*. I had quit. I had quit. For a long, long time. My migraines got less and less. Occasionally they would get real strong, I would take some for a little while. But it was over with. I was over taking it as I used to. Well as you can imagine, that was a very spectacular thing in my life.

Those are personal incidents. Some of the rough times that I went through.

Then I got some other people interested. In fact, some of the people I used to work with - I was doing groups then, too - I was telling people about my experience and they all got excited and interested and said, "Hey! I'd like to do that!"

Fine! Somebody had said to me at one point, "Jacob, you should be doing this. You'd be a natural at this kind of thing."

I said, "Who me? I can't do that kind of thing. That'd be too big a responsibility. I wouldn't know how to handle it."

But this person whom I knew very well wanted to have a trip and I made the arrangements and I gave her a trip and she had a fabulous experience. And that was the beginning. Several people wanted to have a trip. But after a dozen or so had had a trip they were complaining because there was nobody they could talk to about it. Look, you couldn't talk to anybody about it. They wouldn't understand it, they'd think it was a terrible thing or something. So I said, "Fine, let's have a meeting at my house. Everybody who's tripped, we all get together and talk about our trip." We did that several times. They'd talk about it, we enjoyed it very much and one day somebody said, "Jacob, why don't we all take a trip together?" Somebody suggested I should be doing group trips, too.

I said, "What?" They were all clamoring about it. So I said, "Okay, we can try it once. We can all spend a weekend together and we'll have a trip."

There were ten or twelve of us. We had a little ceremony developed and plenty of preparation and security, and I stayed straight. I only let them take 50 micrograms of LSD because I didn't know what the hell was going to come from it. Well, a few of them turned on a little bit. Not very many of them did turn on. But I wasn't going to go any further that time. After it was over we talked about it and had a good time for the weekend, but not much happened.

I decided we'll do it again, only next time I will give them their base amount which I knew from their individual trip. They'd all had individual trips with me. Then we'll see what happens. We did that again about a month later and that was a fantastic experience. That began the whole program of group tripping.

There's the individual trip and the group trip. The evolvement is something I would like to be able to describe. There was so much that went on. It was all experimental, all exploring, everything that we did. We tried this, we tried that, in terms of what went on during a trip. First, I want to go into the development of the individual trip.

In the early days, whenever I had an individual trip, I always had a physician present. He would come in and see the person first and check them out. It was just a procedure that I wanted to explore and see what was necessary and what wasn't. This was mostly for my own feeling of security in case anything happened. He was present the first couple of hours of every trip. These trips were all done in my office. I had a folding bed that I put up and went through a lot of preparation with them first. I explored different things. I read everything there was about what was important to do in preparation for a trip. I tried a lot of them.

A physician worked with me a lot. He liked to work with people throughout the whole trip. I started to do that and then very gradually did less and less of it, until finally I did not work with them except at a point when they wanted me or needed me. He explored on a psychoanalytic basis. He used that model which I couldn't use. It was not my model.

It was less than a year that my doctor friend would come into the office. After that I didn't need anybody. I knew I didn't need anybody. In fact, it was better not to have him. He would try to do some work with the person which was anti what I was doing.

In the beginning I worked with the people on trips - I can't describe what the work was right now. I helped support them in turning on. They got frightened, you know? I'd hold their hands or I'd hold them in my arms and tell them to go ahead, experience it out. I would talk to them in advance about this so that they would know that this was available.

Most of them were blissful trips, but if somebody got frightened with the transition point between one stage of consciousness and the other I would prefer to be close to them. At times I would ask what they were experiencing. If they were in pain or something like that I would ask them to describe the pain, where it was, and go into it. If it was a pain in the stomach, I would say, "Okay, now, think about opening your mouth, and going down into your mouth and describe what you see. It's dark, it's this, that, and keep on going. Describe what you see as you go down. Go all the way down, into your insides." Frequently they would burst into a beautiful world of paradise. The pain would immediately be transformed into ecstasy. Something like that would happen. I tried many different things. As they were coming down from the trip we would talk, and they would talk about where they'd been. You can't talk much, you know, until you're coming down.

Also there was physical contact. It was important in those days that they would have something to resist before they turned on. Or as they were turning on. They were having trouble turning on - I'd tell them first that this might happen - I would lie down on top of them, grab the edge of the bed and say, "Now what I want you to do is push against me." I want you to know, I hung on for dear life. I said, "Push harder, harder, harder!" And they did. When they succeeded in getting me off they were through to the other side! Their report of what happened as a result of that and later what they experienced was just a fascinating thing.

One of the things I had everybody do that I tripped was after or as soon as he or she could sit down and make notes of whatever he or she could recall - write up the whole thing - for themselves, and for me.

Myron: Did you keep copies of these reports?

Jacob: I kept a file of these reports, but some years ago, the file got thrown out. Of all the trips - I had hundreds of them - they would have made a good book themselves.

The screening process and the preparation process: we talked a lot. I had them go through a lot of rituals for themselves - fasting, learn how to do some fasting. I had certain things that I had them read, spiritual literature that was very illuminating and they were able to get it.

Myron: Do you have a few favorites along those lines?

Jacob: Not any more. Not any more, I don't. I don't suggest readings any more, because the people that come to me have gone through a lot of things in terms of reading, and they're ready for something besides reading.

Myron: I'm thinking in terms of people who are just looking into this, and looking for some helpful ways to get started.

Jacob: Very little that I've come across I would recommend. Aldous Huxley's *Doors of Perception* and *Heaven and Hell*, those certainly are ones. Those are the only things I found that were important. I used to give a lot of reading, but that didn't make any difference. This experience is such a very different dimension. They left it all behind very quickly. It did not help in getting them prepared. Their greatest help was their contact with me - talking and experiencing. For the most part the people that I do now are people who make a big difference in the world, with people. They're therapists and psychiatrists, physicians, they're government people who have very high positions and great influence.

Myron: I've always had this dream that you could somehow bring this about, yet we have never succeeded at that at our Foundation (the International Foundation for Advanced Study in Menlo Park, California).

Jacob: They didn't give you the chance.

Myron: I don't know; we brought a lot of stuff on ourselves. We were pretty immature.

Jacob: Of course. I look at the progress I made down through the years and the different changes that I made as a result of my experience - I can't recall them all but I continually changed my procedures and my thinking about it and my ideas about what happened and what could happen; how to set situations so that you get the best possible setting and so that they could get the best possible trip. The most *useful* trip for them.

Some of the rough things that I went through on trips - the roughest of all is they get paranoid and run away. That's scary as hell until they are located. They see me as the devil. No matter what I say to them the devil is trying to destroy them. If I try to get them to take some niacin, which is supposed to bring them down, that's poison. They won't touch it. No way. Or a sedative or whatever. I learned not to do that; I learned to screen better. I could sense after a while whether a person was likely to get paranoid on a trip, or violent, or something like that. And I was alone on all this.

This was such a fascinating thing to be doing! I didn't have to do much of anything at all except provide the opportunity and the material and then to see the fantastic results! The transformations that came in all of those people. It was really something. We went on, I kept on doing it, one or two a month.

Selection and Preparation

Selecting the Client

Myron: What would you look for when you screened? What were the characteristics that were important to avoid?

Jacob: I screened very carefully. I'll try to tell you what my screening process was. A lot of it was based upon experience. Not knowing at first who was a suitable candidate for the kind of trip I did under the circumstances I set up, I would offer to trip people who weren't suitable. As a result I had some pretty paranoid trips. That's extremely painful to go through, to stay with them until they finally come down. Even though afterwards they said it was the most fantastic experience they ever had in their life. It changed their whole life. That always happened when they had those paranoid trips. Painful experiences, weeping, listless; I was very encouraged when they could go through this. One of the things I learned about tripping very early was that we get in touch with feelings we've never been able to experience before and at a depth and a level that we've never been able to reach. That could be fear, it could be love, it could be ecstasy, it could be anything. Just as long as it's feelings - sadness, grief. Lots of times they would start to cry on a trip and cry for the longest time so deeply. To me it seemed so satisfying because they were getting something out. I liked that.

I learned to watch out for my motivations for wanting to trip somebody. To make sure that - I don't know what word would be suitable here - I use the word pure, but it's not the word I want. Clean. That I wasn't doing it for self-aggrandizement or something like that. I learned very early that I am an instrument. I do not bring this experience to anybody. I provide them with the opportunity; they have the experience. They bring their own experience to themselves, and I have the privilege of sitting with them while it's going on.

Myron: I think I've picked up an awful lot of junk sitting in sessions. I was so inexperienced and I'd never been trained as a therapist and I used to get so tired. I'm sure it was my self-involvement - I wanted to do something for somebody.

Jacob: To try to help them. I very soon learned that my traditional techniques of helping people in therapy do not work, they just don't work. Just leave 'em alone! They know what the hell's wrong with them or the God within them knows what's wrong with them and provides them with whatever they need which I don't know anything about and they don't even know anything about. They don't know what their real needs are. All they know is what their wants are. That's true for all of us, of course. (Laughs.) Just how you know you have a good candidate is very difficult to describe. I've tried to relate this many times. I've tried to teach. It's nothing you can teach. Only your experience will give it to you. My intuition was the most important thing, and my stomach. My stomach would respond to something that was not right. Something they would say - or just being with them, no matter what they were saying, because I couldn't trust what they were saying as being them. It isn't them, what they were saying. I would get a vague feeling of anxiety that would stay with me after I had talked to the person and certain questions, certain things that they had said would come to my mind. I would just look at them. Then I would talk to them again a time or two and see if I wanted to proceed more along the exploring. Always I told them this is exploratory until I was really sure I wanted to trip with them and they were really sure that they wanted to take the trip. Then we would arrange for the trip and do some preparation.

Myron: Would you describe it as you would have to feel a certain kind of bond with them?

Jacob: Yes. I would have to have that feeling that I would really like to trip this person. Other factors besides those subjective ones: How much work they have done on themselves in terms of their own individual growth. How long they've been working on themselves. What training they've had. What workshops they've gone to. What readings they've done. What they feel they've accomplished. How far they've gone and what their complaints were about themselves in terms of inadequacies, like, "I know all the things in my mind, but I want to get them in my heart." I can tell in getting their history if they're searching, how far they've gone, how much of it has sunk in. When I get the feeling that I'm really interested in this person, like, "Oh, boy, a trip would do just exactly what they want, what they're asking for!" Then I knew this was o.k. If I didn't get that kind of thing I wouldn't stay with them longer or I would say no, I don't think it's time yet. I had to turn down people very seldom because before they even get to me there's always a selective process going on. They are referred by somebody who knows me and has tripped with me and has worked with me. Before they even get to know who I am or get to see me this person will call me and tell me, "You know, here's so-and-so that I would like to refer to you for a trip."

I would say, "Well, tell me about the person." They would tell me a lot of things - how well you know them, do you trust the person, a lot of questions. Questions are what you want. "What do you know about the explorations that they've made already? You know that we are spiritually oriented. Are they also interested in that and oriented in that?" They know these are questions I'm going to be asking, so that the people that are referred to me are already screened by them as good candidates. It might be the spouse of somebody that has tripped, too. A boyfriend or a girlfriend of somebody or a colleague or somebody who is on the search with them.

In other words they know this person. They've already screened them. The person really wants to have a trip. They know that. They just don't know where to go or how to go and they've heard what great things have come from them, and what great things have happened to the person that is making the referral. They're close, in some way. They'd like to have that happen to them, too.

Then the referring person calls me, because no one can ever give out my name without prior clearance from me. They call me, I get all the information. I say, "Yep, it sounds okay. Tell them to call me and I'll set up an exploratory with them."

And that's what happens. Very rarely do I have to turn anybody like that down. Very rare. Although sometimes I don't have the right feeling about the person and I know that the person who referred them doesn't know much about them, really, but just believes they might be a good candidate. That one I would turn down.

There are these particular questions, some of them I've mentioned that I think of now that I would ask them or explore with them in terms of their state. What their expectations are. What they'd like to get from such an experience. I used to see them six, eight, ten times before I would decide. Not any more. One visit is all I need. One visit with the person for me to experience them and to get the feeling, "Yeah, this is one I really would like to trip." Or for them to get to experience me, for that's very important to them. The feeling of trust that they have in me is extremely important. How do they feel about me? When it turns out that we really make a connection, that's all there is to it, we arrange a trip. No more than that. All the circumstance surrounding the trip, that I'll be talking about some place along the line, too.

So, it's mostly based upon the experience that I've had already and it's mostly a feeling and an intuitive process which I don't see operating, I just see the results which come in my willingness to relate to a person.

Myron: Are there certain kinds of presenting problems which are a factor, like certain kinds of difficulties that a person has that make it a more difficult situation or is it more just a feel of the individual?

Jacob: You see, the point of presenting symptoms, specific problems that they want to have dealt with, doesn't come into the picture. There are no symptoms, really. They just say, "I would like to have this kind of experience because I want to grow, as so-and-so has been doing. I want to get the kind of religious experience that can come out of this thing. That's what I'm looking for."

They will come in, and I'll ask, "What do you want to take a trip for?" Then they'll tell me what's going on in their life that they're dissatisfied with, that they'd like to come to terms with, that they'd like to change. They have lots of anxieties, worried about things - they're not getting along well with their job, with their boss, with their wife, with their family, colleagues or friends or whatever or they've got complaints, presenting complaints. It's not the kind of thing that you find when somebody comes in for therapy and they give you a list of their neurotic symptoms or something like that and that they want to have changed. Sure they want change. Many of them have already gone far enough to learn that it's not the outside that needs changing, it's the inside that needs changing and this is the approach that they want to take for changing the inside. Because when you change the inside what you see outside is different.

Myron: So the people you work with would generally be far more growth-oriented than what the usual therapist works with.

Jacob: Mostly, yes. Every now and then somebody comes from some part of the country that is a person who is referred by somebody whom I've trained out there who does a lot of tripping, too.

Myron: Would it appeal to you if somebody had some unusually tough problem that they were unable to get anywhere with in therapy and they thought that maybe this procedure might be a breakthrough and might be helpful? Would that kind of a case interest you?

Jacob: That's a familiar thing. They say, "I've been working on this for a long time and I haven't been able to get any place with it. Maybe a trip will help me break through it." I've heard this. It could be a specific thing or it could be a general condition that they talk about.

Myron: Most people have a resistance to therapy. They don't like the idea that something's wrong with them and that they've got to go for help. In another case it might be the expense, or whatever, so usually before a lot of people will go into therapy there has to be some really tough problem. Maybe they've got colitis, or maybe they have a serious marriage problem or they know they have a very difficult relationship and maybe they've worked in therapy for a long period of time and haven't seemed to get anywhere. They seem to be really blocked.

Jacob: I see what you're saying. A number of people like that were referred to me and referred by people who know them and know their history. And I say, "Look, I can tell you about something that very possibly may help you break through on this."

Myron: To focus on this issue, maybe they're not even interested in spiritual growth but they just really have a serious problem.

Jacob: Oh, yes, that's right! I never mention the word spiritual to them unless they bring it up. I've had many people, I mean many people who've come to me who have been in analysis for a long time. Some have been in analysis four times a week for eight to ten years continuously. They said they had gotten a lot out of it. However, there was always something that they never could get to. They have taken a trip and in one trip afterwards have said, "I got more out of that one day's experience than I did in my whole eight or ten years or whatever of psychoanalysis." I've done that numbers of times.

Clients with Previous Psychedelic Experience

Here's another one that happens a lot. People will come to me who have already tripped who want to have my particular kind of way of tripping. One of them had tripped at least five hundred times on acid, others who have tripped three, four hundred times, down through the early Sixties, clear up to recent times. You know, *plenty* of trips their own way, who've heard about people who have tripped with me and where they got to so they want to have this kind of trip. We talk about it, and they would be good candidates so I'd say, "Sure." They would have their trip on acid. Invariably these people have said, "I've never had an acid trip before in my life! This is the first time I've ever really had an acid trip."

Myron: I'm real interested in that, because frankly I've had a lot of resistance to Tim Leary and the tremendous effort he made to make it so generally available. I feel that so much of the potential has been missed by kids using it on their own in the way they've used it. There's been a lot of self-gratification, there's been a lot of pleasure experiences and a lot of what Al Hubbard called "sharpening your wits" to reinforce "I'm right, you're wrong." I feel by and large that not too many have seen the real implications. So your experience here really interests me.

Jacob: Yeah. I would always ask them, "Did you feel that you ever got any value from your previous trips?"

They would say, "I got some great insights from it." They would say that in advance. But afterwards they would say, "No, nothing like what I got this time."

Myron: I think that's really marvelous. It says a great deal for you and your procedures. And it confirms some of my own hopes in this area. Did you keep any kind of records where you might be able to give some kind of a numerical assessment for this sort of thing? Like, how many individuals came to you who had many, many acid trips who arrived at this conclusion as a result of a single trip?

Jacob: I didn't keep any records but I can give you a fair estimate. Looking over more than 3,000 people who have tripped with me individually and in groups I would say that between five and ten percent have tripped before. That's on psychedelics, not just grass. Certainly five percent have tripped; some a little bit, some a lot. It's those who have tripped a lot - well they will all say that the trip they do with me is very different, very different.

Myron: You can say that that's just about universal?

Jacob: Yes. For those who have tripped before on acid or any of the psychedelics or psychoactive materials even, except for grass. Yeah. Once or twice a number of them - I can't recall now how many - have had very bad trips and came to me to have a trip under these circumstances. Usually where they were interrupted, and unable to get all the way through it because somebody took them off to the hospital and they were given Thorazine or some kind of shit like that. They didn't get a chance to really complete it, to go through all the bad spaces that they had to go through. They would come to me and we would trip.

Under my circumstances I helped them through their fears so that when they came out they were really reborn. That's Stan Grof 's whole model, that's a rebirth experience. Transformation is rebirth and all that.

Clients in Therapy

Myron: Do you think you can make an estimate of how many had been in extensive therapy who as a result of a trip with you found that they had made a really profound gain compared to the therapy they had previously been in?

Jacob: Yeah. How many had been in therapy - a lot of them. Let me see if I can say how many. Eighty to eighty-five percent had been in therapy before. Some of them were currently in therapy and wanted to have this experience. I want to come back to that, so you remind me of that. Out of that eighty to eighty-five percent, whatever it is, all of them said they got much more out of their tripping.

Now, they're not putting down their therapy. In fact, this experience illuminated the insights that they got from therapy but didn't get very deeply. It validated their therapy. For many people, too - I don't know how many, it would be hard to estimate this - it brought them to the realization that they wasted all of their God-damned time; they didn't get a thing out of therapy. They worked hard at it, stayed long at it, many of them, labored at it, and thought there was something wrong with them. In fact, they had just gotten with the wrong person, that's all. If anybody came to me that was in therapy I first stipulated I cannot bring you this experience unless you get clearance from your therapist. There was an immediate screening process taking place. There were those who said they couldn't do that, they just didn't want to tell him about it.

I said, "That's quite a commentary on the relationship you have with your therapist. I can't do this. I will not do it. If you tell your therapist that you want to do this I need assurance that he agrees that it's okay for you to do it. I'd like for him to talk to me if he wants to." No, I stopped doing that. I didn't want to be identified.

Myron: I was going to ask you about the exposure.

Jacob: I want the therapist to know that the person I'm talking to about this has already agreed not to reveal my identity to anybody without prior clearance from me. That's the first requirement I give to anybody.

Myron: So if they went back to their therapist to get clearance they would say, "I've found somebody that's real good to take a trip with," and the therapist asks, "Who is it?" They'd have to say, "I can't tell you."

Jacob: Right away that would bust up the relationship.

Myron: I can see where a lot of therapists would really get on their high horse about that. On the other hand, were there any who got to know you and would keep the trust and even be willing to refer their patients to you?

Jacob: Most of the therapists who would do that have tripped themselves. I always warned the person who was in therapy that, "I want you to understand and realize that it's quite possible that after you've had your trip you will terminate your therapy." Invariably it happened. In a very few cases they could keep on working with the therapist. They could do that if the therapist had tripped. But you cannot trip and work with a therapist who hasn't tripped and get any value out of it. You can't relate back and forth. You can't trip as a patient and work with a therapist who has not tripped because he has not had the experience and you cannot relate to him about it. It ends up that I can only trip people who are in therapy with a therapist who understands tripping and is willing to refer.

Let me mention something about my original position when I first started out. I had the traditional psychological or psychiatric attitude towards this stuff. This is dangerous, this is bad, you shouldn't do it, and anybody who does it is crazy, and all that kind of stuff. That was my position in that regard.

There's no easy way to satori. You've got to work hard and you've got to suffer. I was like the typical Christian who didn't have much confidence in grace. Yet I knew what grace was. I did experience grace many times. I had to overcome all of those prejudices first before I could really explore honestly and openly. And of course my first trip dispelled all my doubts. My own first trip. Since then there was never any problem.

Myron: Would you care to say approximately how many therapists you have provided the experience for?

Jacob: In all categories - psychiatrists, M.D.s, psychologists, psychiatric social workers, transactional analysis people, all the different schools that exist where people see patients whether they're licensed or unlicensed, there's quite a spread of all of them - altogether, a hundred and fifty. That's what comes to my mind. It's over a period of fifteen years since I've been really doing it.

Myron: And these are all people who would have a practice of their own where they would be counseling others.

Jacob: Right. People-helpers - that includes nurses, physical therapists, people who are very important to other people. At times I would get referrals from them.

Myron: Of the roughly 150 people-helpers you have worked with, how many are actually psychiatrists and psychologists?

Jacob: I would say about one-fourth. The others are psychiatric social workers, family counselors, professional helpers like that.

Myron: Well gosh, you've started a real significant movement here.

Jacob: (Laughs.) It extends very much around the world, really.

Myron: It's been kept very, very quiet, it seems to me.

Jacob: The selective process has helped with that. The security practices that everybody's imbued with right from the beginning. That's what's important. I've been able to function this way. Yes, it's underground, and all of that. I've been able to function this way for all of these years because I trust the people and they know about our security situation. A few people have broken security. It has happened. Nothing has come from it, of course. They've told somebody who tripped them.

Security Problems

Myron: Security must have been a terrible problem. Can you say more about what it's like to work under such conditions?

Jacob: We were always security-conscious and we made everybody who came in contact with us security-conscious. Most people were able to really be ethically security-conscious and a few weren't. The few who weren't who talked about it, maybe blabbed, talked unnecessarily or identified people - no harm has ever come from that.

You see, again, a spiritual trip is what's involved here. This I have to say - it's the only way I know how to talk about it - what I do and even how I do it is not up to me. I'm guided. I can't define that, I can't explain it. I know that that's true. If I wasn't supposed to be doing this, and I've said this before, I wouldn't be doing it. If God didn't want me to do it He would have stopped me a long time ago. I have a lot of faith that that's true. At the same time I keep a close eye on my integrity and my security. Everybody else's security is bound up in mine. We're all in it together.

I definitely have suffered, I have suffered considerably with fears, what I call "just in case" fears or "what if" fears. What if we're sitting there, laying there and having a trip, you know, everybody's all laid out and stoned out of their God-damned mind, their pupils are as big as saucers, and somebody knocks on the door and it's the police raiding us. I don't know how many times that's come across my mind. What if somebody died on a trip? What if - I don't know, all the "what ifs" that I had - what if somebody freaked out and ran down the street screaming? *That happened*!! Paranoia! Everybody has it, I know, and I have it! If I hadn't been doing *this* to be paranoid about, I'd b e doing something else to be paranoid. It's only since I've taken the Course in Miracles that I've gotten over my guilt and my fears. Many years and many times I'd be in much agony falling asleep, and wake up in the morning and have it hit me. That's true. I've looked at it and I've said, "Jacob, for Christ's sake what are you exposing yourself to all this shit for? You don't need it." Then I'd look and I'd say, "Look at the people. Look what's happening to them." I'd say, "Is it worth it? Is it worth going through all of this shit for that?" Inevitably I'd come back with "Yeah, it's worth it." Especially at the end of a weekend when I'd see what fantastic things have happened to these people. I would say clearly to myself, "Jacob, it is worth it! Whatever you have to go through. It's worth it to produce these results!"

Security has been a terrible problem. It hasn't been a problem in that sense, but like I'm describing now. What I've gone through because of fear of discovery. This is a part of security. Actually, my worst fears in every situation have been realized. I have said many, many times, whatever you are afraid of never happens. And I know that's true. And yet sometimes the exact incident that you're afraid of happening does happen. However, what you were afraid would be the consequences did not happen. So what you're afraid of didn't happen. That's happened in my life a number of times. Some of them have been in connection with psychedelics, with what I'm doing.

There are those people who know that I'm doing something. I believe they know the kind of work I'm doing and know that it's under very good control and a creative process. They don't bother me. They won't do anything to me. You'd be surprised at the different walks of life people have come from for tripping.

Preparation

I'll bring my analogies in here at this point. When I'm talking about a trip to a person who hasn't tripped and they want to know, "What's it like?" It's hard to describe what it's like but I have a couple of analogies that I use.

One is, imagine that you're on a stage, a very large stage, around stage, circular. You're standing in the center of the stage. Around this stage is a huge curtain, very, very high and it's closed and where the curtain comes together there's about say three feet of space, of an opening. You're standing in the middle of that stage and you're looking out through that opening. Everything you see is the totality of your experience of yourself.

What happens on a trip is by some mysterious means the curtain very gradually is pulled back. Very gradually. It's pulled back until it's pulled all the way around the back and you're given the opportunity to see everything that's been there all the time but you couldn't see it before because there was a curtain. All the different levels of experience that it's possible to have, you have. All the different truths, all the different things, you have. You experience it. Then, as you start to come down, very gradually the curtain gets pulled back around until you're all the way down.

When you're all the way down, the difference is that before, you had about three feet of space that was open to look through. You now have about fifteen feet of space. You have really expanded your awareness, which is what they call these materials, awareness-expanders.

Myron: The curtain might have even gotten a little transparent.

Jacob: Yeah, (laughs), that was what I was going to follow with. In addition to that you have a lot of memory of what you did experience before. So in a sense that's true, the curtain has become almost transparent. You don't remember everything, you don't need to remember everything. You don't need to. You remember everything you need to remember.

There's another analogy that I use, too. It's similar to that. That is, imagine a castle, a huge castle, very large. Many rooms, many turrets, many levels of it. There's only one way to get into this castle, and that's the front door. The front door is *solid steel*. *Impregnable*. You can knock on that door all you want. You can do everything you can to tear it down. You can't get it down. Every now and then you might somehow or other move it a little bit to get a glimpse of what's behind it, but that's all. There's no way, and you've tried every way possible to get into that castle. Which is yourself.

What happens on a trip is by some mysterious magic means this door is dissolved, and you have the opportunity to go in and explore that castle. Any place you want. You go in and you look around, and you find many, many wonderful places, strange places maybe, scary places and all that. You can go to the top and you can go to the bottom and you get a sense of what the totality of yourself really is like. As you come down, what happens is that the door somehow or other gets back up there. But that's all right, because you have a memory of what possibilities are there and what you've experienced. The biggest experience that it brings to you is that it connects you with feelings that you've never been connected with before. They are now open to you. Not on the level or the intensity that you had in the experience but certainly much more than they ever were before. That gives them an idea. "My God!" they say. "How soon can I have one?" (Laughter.)

Myron: God, Jacob, those are so good. I think of places where I can use those analogies myself. Do you have any objection if I use them?

Jacob: It's the greatest privilege in the world for me to be able to share them, so if they're of value to other people they're welcome to them.

Myron: One of the problems that you run into is that very often you get people who have rather powerful internal conflicts and it's really difficult for them to confront them and they'll dodge and go off in different directions. Did you ever do anything to try to encourage them to confront that sort of thing? Similar to the way you described if it manifested as a pain - you had a beautiful technique for dealing with that. Did you have some other techniques along those lines?

Jacob: Yes, yes. Whenever I was aware of anything like that - whenever they'd get really frightened - I'd ask them to, "Look at what you're afraid of, just look at what you're afraid of. All you have to do is just look at it; don't do anything about it, just look at it. Just keep on looking at it and just tell me what you experience when you're looking at it." Most of the times they'll go off into some kind of a visual trip. Experience something. But they were not experiencing a specific block that you do experience consciously. It wasn't that. It was a painful fear. That's what I had them live with and stay with until it became transformed. As it did, the block was gone. I don't think we even knew what the block was. It was not a specific fear. It seemed to me at the time that it was an *accumulation* of all the unfaced fears that was being expressed at that time. By facing them they dissolved them - to some degree at least.

Myron: One of the marvelous things about this is the honesty - that once you're willing to face it, it becomes resolved. This is one of the major uses of these substances, I think.

Jacob: I use an analogy with them when we're going through preparation. You know, if you're walking along and there's someone behind you and you're worried or scared about it and you start to run, the more you run in fear from it the greater the monster becomes. Once you stop and turn around it turns out to be some little silly funny thing, and their fear disappears. There're many little anecdotes like that that I would give in preparation for trips.

Photographs

One of the things I have them do for the trip is to get a bunch of pictures from a list that I give them. These pictures actually as you'll see are a history of their lives. They go back home or get them wherever they are or write for them. They get all the pictures that they can and bring them to wherever they are. Then I ask them to select the pictures in a particular manner which is really very important. I say, "Give yourself plenty of time. First let me give you the list of pictures that I want you to get." Here's the list:

1. Starting with the pictures of themselves, one at age two and one every two years thereafter through adolescence, sixteen or eighteen.
2. A picture of their mother and a picture of their father when they were young but they can still remember their mother and their father, and a recent picture of each.
3. Same thing about each of their siblings, an early one that they remember that way and a recent one of their siblings and their families if they have one.
4. A picture of a grandparent that was significant in their life.
5. A picture of any aunts, uncles, or cousins that were significant in their life.
6. If they're married, I ask them to bring some wedding pictures because wedding pictures usually have all the relatives and it gives them a chance to see them. If they don't have any pictures I'll say a picture of the woman you married either just before you married her or when you got married, an early picture. And a recent one of her or him, as the case may be.
7. If there are children, a picture of the children when they were about two years old which is when they begin to start to have a little personality of their own. And a recent one of each. And if they are married, with their families. And even if they're not married, a picture of any woman or man who has had great significance in their life. Lovers, current or past or whatever.
8. Other significant pictures.

I ask them to select the pictures in this manner: Gather them all together - boxes, albums, however they are, and put them in front of you, and start with one. The top one or anything like that. Pick it up and look at it. Just look at it to see what you experience in connection with that picture. Look at it a little while. You may not experience anything. It's all right. Put it aside, pick up the next one, then look at it. If it provokes any memories, kinda sit with the memories a little bit, let them go where they want to go. Whatever feelings you have, allow them to be there. Whenever you come across a picture that's on the list, set it aside in a separate pile. Go through *all* the pictures you've got, every single one of them, doing that. You may have to have two or three sittings to do it. I ask them to do it no further away than a week before the trip, as close to the time of the trip as they can. I want to tell you something. That really turns them on. When they come they're in the middle of their trip.

The Individual Trip

Myron : Let's get into your procedures.

Jacob: All right. I'll start with the individual trip first, because the group trip follows the individual one. The first trip is always with LSD. I like to start at eight o'clock in the morning. I like to do it preferably in their own home, if it's convenient, secure, and nobody's going to be there, nobody's going to interrupt, and it isn't too far away for me to go to. (Laughs.) I get there maybe a half hour before that, before eight.

I set up my equipment. My equipment consists of headphones, two face masks, a cassette player and separate recorder, tapes for music, and a special cup. (Jacob shows the box he takes along with him.) I carry these along with me which is part of my ritual that I have. I talk about the transformation experience and how the cup is always a very important symbol of the transformation experience.

I have this setup with the earphones coming out of this machine. This is the way I play my music to them. Music is all on cassettes. The records scratch and they don't work very well at all. Then I have another tape recorder in there which is used to record everything that's said. I record the whole trip. I have a remote control here that I use so that I only turn it on when something's being said.

These are some of the things that I go over with them. The structure is first. Structure is a very important thing, and what structure is, is a set of agreements that I ask them to make with me. These are the things that I ask them to agree to with me:

1. They will not leave the house where we're having the trip at any time during the trip without prior clearance from me.
2. They agree that there will be no physical harm or violence to themselves or to me or to anything else in the house.
3. Reiteration of the security requirement. They agree they will not reveal to anybody else where and with whom they had this trip without prior clearance from me, ever.
4. I ask them to agree - now if this is a woman or somebody gay - I ask them to agree that there will be no sex taking place between us. I'll explain the background for these agreements in a minute.
5. The last one I ask them to agree is that at any time during the trip if anything is going on and I tell them to stop it, stop doing it, and I make clear, "This is under structure; it's not just a recommendation or suggestion," they agree that they will stop it. Or if I tell them to do something and I make clear it's under structure they agree that they will do it. I tell them to look at this one very, very carefully, because when they agree to that they are virtually putting their lives in my hands and the only thing they have to go on is whatever faith they have in me - that I would never let them do anything that would be harmful to themselves, nor would I ever require anything of them that would be harmful to them. These are bills to faith. That puts them back on their faith, see.

I review it, and then I say, "Do you have any questions or qualifications or anything that you want to know about it?" When they say no, I say, "Do you agree to abide by this structure?" They say, "Yes." I say, "Thank you."

Now, the first one, not to leave the house: I don't want them wandering around without prior agreement. Sometimes when they're coming down from a trip if they want to go out and walk around because its so beautiful, fine, I'll walk with them. They ask and they check with me.

Physical harm and violence: Sometimes people are afraid they're going to be angry, they're always talking about the unexpressed anger that they've got. They're afraid that might happen so when they make that agreement they feel safe about the anger, they're not going to destroy anything or hurt anybody.

The fourth one about sex: Sometimes women get real turned on. Sexually they get really connected with their sexuality and they're scared, they don't know what to do with it so they'll tend to squelch it. I don't want them to do that. I want them to find it and hang on to it and know that they're safe, nothing's going to happen. The same thing with a gay person. If it comes up, let it come up, what the hell.

Okay. They've agreed to abide by this structure. I ask them to read this, a late 17th century prayer. It's the only thing I've ever found down through the years that really is the most suitable for beginning a trip. I ask them to read it quietly to themselves once and read it through a second time:

> *Lord, I know not what I ought to ask of thee;*
> *Thou only knowest what I need;*
> *Thou lovest me better than I know how to love myself.*
> *O Father, give to Thy child that which*
> *he himself knows not how to ask.*
> *I dare not ask either for crosses or for consolations;*
> *I simply present myself before thee,*
> *I open my heart to Thee.*
> *Behold my needs which I know not myself;*
> *see and do according to Thy tender mercy.*
> *Smite, or heal; depress me or raise me up;*
> *I adore all Thy purposes without knowing them;*
> *I am silent; I offer myself in sacrifice;*
> *I yield myself to Thee: I would have no*
> *other desire than to accomplish Thy will.*
> *Teach me to pray.*
> *Pray Thyself in me.*
> *AMEN.*
>
> - Francois de Salignac Fenelon Archbishop of Cambray, 1651-1715.

Then we have a dropping ceremony, and I explain the cup and I have water in it and I have the capsule with their medicine in it, too. After they've read the prayer then I give it to them. I've already explained the significance of the cup as a symbol of transformation all the way back to Jesus and to earlier days and all that kinda stuff. I have them take the cup and the capsule, swallow the medicine whatever it happens to be, and drink the water from the cup.

After this dropping ceremony I ask to see their pictures. I have them organize them according to this list, their own pictures first with the youngest on top and the oldest one on the bottom. Their youngest age and the oldest. Same with the mother and father and all the relatives if there's any chronological period of time that's involved. The last one I ask them to look at is their wife or lover currently.

Just before that I organize them all in this fashion: First the pictures of themselves, then the mother, then the father. Now, some of the other pictures will have mother and father in them, too. They may have some very significant picture show up that isn't on that list for mother, father, family, or something like that. A house that they lived in or a pet that they had, goodness knows what, maybe an army picture. Whatever really gives them an emotional charge, positive or negative. That's what I call other significant pictures. They're to pull those out to really get to cover the ground there. Sometimes they bring too many, I screen them out.

Now, once they've dropped the medicine, I say, "Let's look at your pictures." They'll show them to me, and I arrange them in the order that I want to use them, and that's it. We don't take them apart and look at them. I set the organization and have them identified into their stacks, because we'll be doing that later. Then we sit and we talk. I ask them if they've had any dreams the night before or whatever. When they have them I say, "Well tell me about it." I just want them to tell me the dream. I frequently get something out of the dream.

I explain to them, and I've already talked about this before to them but I say, "You know when you go along through the transition from one stage of consciousness to another one sometimes you run into difficulties. If you do, like if you get frightened or something like that, all you have to do is put out your hand. I'll see it, I'll be sitting right there. If not just say, 'Jacob.'" Their hand's out there, and I'll go over and I'll take their hand and put it in mine. No talking, or anything like that. I just hold it nice and firm and solid. God, what they say afterwards about what happened during that holding the hand, what a tremendous experience they had. If they want me to I'll put my arms around them and hold them in my arms. I encourage them when they get frightened to stay with it, don't try to do anything about it, just let yourself be afraid. I explain to them I will be here all the time. I always have a security bucket and a package of kleenex, in case they get nauseated they've got the bucket there.

We'll sit and talk about different things until they feel themselves starting to turn on. Then, fine, I ask them to go to the bathroom and empty their bladder, then come back and lie down. Then I put their eyeshades on, the earphones on, and cover them nice and cozy and comfortable and turn on the music. I tell them that I'll check in with them after an hour to see if they're turned on. They turn on with the music. Beautiful turn-on music, too.

Myron: How do you tell if they're turned on?

Jacob: What I do is I've got a microphone, see, and I'll turn on the microphone and I'll talk. I'll say, "______ (whatever their name is), do you feel turned on yet?"

They'll say, "Oh, yes."

I'll say, "Good. Have a good trip." And I just turn off the thing and let it go.

Or they'll stop and they'll think and say, "I'm not sure."

I say, "Are you as turned on as you'd like to be?"

Sometimes they say, "No, I think I could be more turned on."

I say, "Good, I'll give you a booster."

Or they'll say, "Gee, I'm really not sure. I haven't done this before. I don't know what it is to be fully turned on."

I say, "Okay. I'll check back with you again in fifteen minutes." I don't think they are, but I want to check back anyway, because sometimes they might turn on, it takes an extra fifteen minutes. I check back with them in fifteen minutes and I say, "Are you turned on now?" They'll still be questioning. As long as they're able to question they aren't turned on enough, I'll say, "Well, I'll give you a booster."

I check with them again thirty minutes later. Most of the times they are already turned on. If not, I give them another booster. If they're not really turned on I'll keep going until I check in and they say, "Oh, yeah." Sometimes I watch them, I can tell from the way they are. I can tell they're really stoned. They're going through quite a trip.

Myron: How long do you wait for the second booster?

Jacob: Thirty minutes. Between boosters, thirty minutes between any boosters until they're really turned on. A booster would go 125 micrograms unless not a thing's happening, they feel pleasant and all that but not a thing's happening. Then I'll give them 250 micrograms. I mention to them, "Look, sometimes you get real turned on by a piece of music and it's a great experience and it ends and you're kind of disappointed. All you have to do is say, 'Play it again,' and I'll play it again for you. You go right back out again." I tell them that music is the vehicle that takes you to all the different places you go on your trip. Music is the vehicle that takes you to all the different places.

Myron: Isn't silence the vehicle sometimes?

Jacob: Oh yeah. I say, "If you ever want to be quiet, have silence, let me know." Most of the time they want the music. Oh yes.

Sometimes I'll just not play anything for a while but in just a little bit they'll say, "The music's off." You've never heard music in your life, really, you'll see that you've never really heard music in your life until you've heard it on the trip. Which is true, everybody knows who's had that. I tell them, "Anytime I'm playing a piece of music that's not consonant with where you are, that's bothering you or you don't like it, just say, 'Change the music,' and I will." Once in a while that happens. Most of the time with the kind of music I have they dig it all the way through.

I can tell when they're starting to come down because until that time they are absolutely still. Every now and then I've got to get down on the floor to look to make sure they're still breathing! (Laughs.) I do that as a kind of a ritual. I don't do it because I'm scared any more. (More laughter.) When they start to come down, they start to move around, they may want to go to the bathroom. Sometimes in the middle of the trip they want to go to the bathroom. That's fine, I take them in the bathroom and stay with them unless they want me to go outside. I ask them before they come out to stop and look in the mirror, the bathroom mirror. Just take a good look. They do, you know, God they report things - whatever they saw and all that. Later. Not during this visit. I take them back, lie them down, put them back.

All right. When they have come down enough that they're able to talk but they're still hallucinating a little bit - that may be five, six hours into the trip, around that time - some may be a little bit earlier, some may be a little bit later, seven or eight hours - and they're functional, they can move around, I have them get up. I've told them this is what'll happen. I have them get up and they go sit down at a table some place and we do the picture trip.

What the picture trip is, I start out with pictures of themselves. I have them in front of me. I take the first one and I hand it to them and I tell them, "Just look at it, just look at it and see what you experience. Look at it as long as you want to. When you're through looking at it, hand it back. If you have anything to say, fine. Say it. If not, you don't have to say anything." One at a time I hand them the pictures. The pictures, they don't react much to the two- to four-year-old pictures. Some time around the age of six is a very significant picture for them. That's the point in life where we lose our naturalness and we start taking on the acts of the world and behaving the way people tell us to and start squelching our own naturalness. Frequently they get to that picture and they start to cry. And cry and cry and cry. "Gee, what an unhappy face!" Or they say, "I don't know."

I'm taping everything that's being said. They'll do a lot of talking and a lot of crying. And a lot of ruminating, and remembering. This talking is very important to them later on when they go back and listen to it. It reconnects them with their whole experience. I give them the tape. After we've gone through all the pictures we just sit around. If they want to listen to music some more, fine. Listen to music. Then maybe about four o'clock in the afternoon, say, I arrange to have the babysitter come by.

I don't like to leave them alone on the day of their trip. I want to have somebody stay and spend the evening until they go to sleep or spend the night. It's got to be somebody they know, love, and trust as well as somebody who has tripped if it's at all possible. Because somebody who has tripped knows how to serve somebody who's just tripped without asking a whole bunch of stupid questions that they can't answer. Just takes care of them, and just listens to them talk if they have something to say. Or leaves them alone if they want to be alone. I tell them, "I will not leave until you say it's okay for me to leave." The person who comes as their sitter may be their wife or husband. They may not have tripped but they may be the most suitable person. I brief that person about how to take care of things.

Myron: Generally in a marriage you have the partner absent during the trip?

Jacob: Only me and the person on the trip. Unless I'm doing a couples trip, but they've already tripped individually first. Although when the other one comes in there's quite a bit of relating that goes on because this person is so transformed and has come to a new level of feeling of love about their spouse or lover or whoever it may be. Then, oh, I might fix them a little plate of some fruit, crackers or cheese or something to eat, you know some sensory thing, have a glass of wine, something like that. I stay with them and the sitter until it's okay for me to leave. I pack up my stuff and I go on home. And that's it.

I'm available for them to see or to call and I leave my number and everything. If anything comes up they want to call me about, anything at all, I tell them, "Don't hesitate at all, call me any time."

That's the individual trip.

The Group Trip

Jacob : One of the things that I've had a lot of experience with is the group trip. People get a great deal out of the group trip. It allows them to try a lot of different things, and connect with a lot of other individuals. The way we've worked it out, it lets them go through a progression of growth.

One of the most important things for a group trip is to have a nice setting. I have a very good friend in Washington, D.C., a psychiatrist who loves this work. He has a place on the western shore of the Chesapeake Bay, not too long a drive from the city. It's perfect - a nice view of the water, lots of trees, secluded, excellent security. We've been running group trips there for a long time. I used to fly out every month until his own people got so experienced it wasn't necessary any more.

We generally have between ten and twelve people come, trippers, and three gurus who stay straight. They all arrive Friday evening around eight o'clock and they greet each other with love and joy since they haven't seen each other since the last trip they had together. They meet the new people and the new people get to meet all of them. We only have one new person a weekend unless there's too many backed up. Then we'll take two new people a weekend. There'll be some snacks set out there for them to nibble on and they'll have some wine. It's a nice occasion until they all arrive. When they've all arrived and greeted each other, then we all gather in the living room and sit around the room.

The leader makes announcements about things and all of that. Then we induct the new people, the new person or people, into the structure of the group. It's the same set of agreements except no sex takes place during the weekend. This is a very important thing. I want to tell you how important this is. I'll tell you right now, otherwise I'll forget it.

The experience evokes such a tremendous feeling of love and closeness that people love to be close and hug each other and love each other. They have love puddles where they all get together and just hug each other and love each other. When they know there's not going to be any sex nobody's worried about what might happen. They can let go to their really loving feelings without being concerned about, "Is he trying to make out?" or, "Is she wanting me to make out?" or whatever. All these crazy thoughts that occur to people. Then they just have a marvelous time. That's after they've all come down, you know. But the instruction is that no sexual activity take place at any time during the weekend.

The last one is the same as the last one I gave about the individual trip - do what I tell you to do or stop doing what you're doing - it's the same structure. But now it's with the group. They're being inducted and everybody else is renewing the structure for themselves. The leader presents them with the questions and asks them if they agree and they say yes. He says, "Thank you," and they say, "Thank you," and then they go on.

The next thing is that the leader may read something or talk about something that he's currently working on or something like that. Not really much more. He asks, "When you talk tonight, I want you to just talk out of your experience and tell whatever's going on in your life that you want to share with us, whatever you're hoping will happen this weekend." There's a variety of things that he mentions.

By the way, the new person has already been briefed about the whole procedure for the whole weekend so they know what to expect. Then the leader says, "Who would like to start?" Somebody raises their hand and starts talking about where they're at, what's going on, what's happened since the last time. Anything that occurs to them. We ask them to talk to the whole group, not just talk to the leaders. We don't go around the circle, because no one should feel under pressure. Whatever they want to say, and as much as they want to say is fine.

It's only when you're ready to speak that you do it. There are frequent breaks. After about four persons there's a break. They all get up and pee, drink some water, have some more nibbles or something and talk and catch up on things until we've gone all the way through everybody. That includes the three staff. We all participate; we say what's going on in our lives, what we're into. And, as I've explained it to them, each comes there as a separate link, and in this process they forge the link into a chain, by this process of sharing with each other. You learn a lot, too. You sure do. And we see how far so-and-so has gone since the last time or whatever.

It takes a number of trips before you get to trip with everybody who comes, and you don't get to trip with everybody who comes because some people come once every six months or once a year so they're tripping with different people all of the time. There's always somebody there that they know from other trips, two or three maybe. So you really get the experience of a whole bunch of people.

Then the leader talks about going to bed - what happens is when they're ready to go to sleep, they stake out their pads where they're going to sleep. Pads with blankets. They pick places all around the house. When they're ready to go to sleep, they smoke some grass sometimes to help them to go to sleep. Whatever. It's all okay. When they want to go to sleep they go over to their pad, lie down, put the earphones on and there's music playing, going-to-sleep music, until they go to sleep. They wake up early in the morning, around 6:30, and complete their toilet. We ask them to be very quiet, not silent but quiet and reflective. If they meditate, do some meditating. Move around outside, just not a lot of unnecessary yacking. They follow that pretty well.

One at a time each person sits down at a table with me and the leader and we go over what medicine they're going to take. (The various agents available and their effects are described in Chapter 5.) We decide what they're going to take and how much. It depends upon what they're trying to achieve, what they're looking for, what they hope will happen and what kind of medicine they think they want, if they've had different ones. Frequently they know just what they want to take, and we've already got the standard dosage for that person. Fine. We put it in an envelope, until we've gotten everybody.

We all gather in the living room again and we have our dropping ceremony, which is a very nice ceremony. After everybody's dropped, they wander around, they're quiet. We ask them to still be quiet, until they feel themselves starting to turn on. Before that they've staked out tripping spaces, which may or may not be different from the sleeping spaces. If there's two people coming together as a couple we want them to trip in different parts of the house, whereas they might have slept together.

When they start to turn on, they go to their pads, lie down, put the eyeshades on and the earphones on and there's music playing already. They just lay there until they turn on. The only time we ever hear from them is when somebody feels they haven't turned on and want a booster. They'll call one of us over. Or if they have to get up and pee later on. We've got it down now so we know everybody's dosage, so we rarely have to give a booster. They lay on their pads, and we're in the kitchen sitting and talking and all that stuff and waiting, just being available.

Myron: All the time they're really in it, they're laying there listening to music?

Jacob: Right.

Myron: You don't encourage any interrelationship.

Jacob: No! We don't want anybody to talk. Sometimes, somebody when they have MDMA, Jesus Christ, you know, they want to hold hands, it's so loving and all that. That's all right. If somebody doesn't want to hold hands, they're on a different material, all they have to do is hold their hand back and everybody respects their position. The MDMA people like to get up and do some hugging and then we set them right back down. We'll all hug them, they'll call us over just for a big hug. They're so full of love, it's really fantastically beautiful.

By middle afternoon they start coming down and they start moving around. They'll go outside in the patio or just sit around in the house and they're still turned on or coming down, whatever. Later on there are some things put out on the table - salad, some crackers and some fruit and some things for nibbles. Then when they're all down, when they're all down enough so that they're quite functional, we all gather in the living room and we have our champagne ceremony. All of this is tradition that's built up over the years. It's hard for me to trace all the different activities that we went through to get to this point. But this seems to be the most fruitful. The old timers who come back to trip with us once in a while who went through that early stuff say this is a helluva lot better way to trip.

After the champagne ceremony we have dinner. After dinner, we'll all sit around and laugh and giggle and tell jokes and have fun, or sit quietly and just observe the others that are still tripping. Or if they want to be alone they go off somewhere to keep going on their trip. The music continues so they can listen to it if they want to, until they're ready to go to bed. When they're ready to go to bed they find an empty pad and lay down. There's no staking out because they're pretty stoned. They get up in the morning oh, by 7:30 anyway. We have breakfast at nine. We ask them to be quiet again in the morning, too, because their trip is still going on even though they're not stoned.

After breakfast they all gather in the living room again. And the leader usually has a reading. I always had a reading, it's a nice thing, very appropriate, no matter what the hell you do, it's appropriate. From where they're at, everything's appropriate. They go around again and they talk about what happened.

One of the last things that's said on Friday night - it's traditional, too - "I want you all to now take a look at yourselves, close your eyes and look at yourself and just see what you're experiencing now, that's all. Just see what you're experiencing now." They give them about a minute to do that and then the leader says, "We'll ask you to do this again on Sunday morning." And he does. This sharing is the high point of the trip for everybody. Not only have they had their trip, they're going to have ten other people's or eleven other people's trips, too. And the *feeling* and the *sharing* and the talking out of where they are, sometimes the deep crying that comes out. Everybody is just pulled into it. And we *are* one. Until then we do not know what happened on anybody's trip. We don't know! That's our payoff for having been there all that time and handling it like we do.

When they're all through we have lunch and we get ready to leave. By mid-afternoon they go home. They sign up for the next one they want to come to. They are available every month.

Myron: So if you only have it once a month and you can only handle ten to twelve, probably you have a much larger group moving in and out of the group experience.

Jacob: Oh, yes! Oh, yes!

Myron: What would you say is sort of a working number?

Jacob: The active members of the group are about 40 or 50 who are coming every third or fourth month. There are about 100 who come less frequently. Something like that. You see, we have a priority list. The priority list is this. First trippers have first priority, the first time they're coming to the group. The second priority is somebody who hasn't tripped for a long time. Third priority is somebody who is in some kind of space where they really need a trip, want very much to have a trip, and we agree that it would be a good thing for them to have it, if there isn't a possibility for them to have it another way. But they don't generally want to the other way, they'd rather trip with the group anyway. And then there's another priority: we try to keep a balance between men and women.

Well, that fills the group, you see, if we get through all of those priorities.

Materials and Doses

Myron : I'm interested in the different chemicals that you've run across. What kind of significant differences, if any, do you see among the different agents?

Jacob: We have a spectrum of materials that we use. They've been screened out. I've tried many of them, explored many of the new ones that have come out. I'll list the ones that are most suitable for a group trip as far as we're concerned. There are many more but most of them will do the same thing as these do and most of them won't do as well as these do. One of them is LSD. Everyone first has an individual trip with me which establishes their LSD dose level. Other materials we use are the *Psilocybe cubensis* mushroom, dried. And mescaline - we don't use peyote. MDA. Ibogaine. Harmaline - we call it *yagé*. It's the active ingredient of *yagé*, that's the harmaline hydrochloride[1]. MDMA, Adam[2]. I have not adopted 2C-B. It just doesn't seem suitable for a group trip at all. Or DOB or the TMA series. TMA-2[3] is the one that was thought best for an experience.

Myron: I'm surprised that DOB hasn't worked well.

Jacob: We've tried it, and some of them will say, "Yeah, it was a nice trip but I get more out of ___ or I'd rather have ___." It doesn't do anything more for me than one of these others. I like to keep it down to just a few.

1. Harmaline is called yage in error. It is not the active ingredient in yagé. DMT and/or other tryptamines are. See Ott. Pharmacotheon. Kennewick, WA: Natural Products Co. 1993, page 260. footnote 3.
2. The code name "Adam" for MDMA was a term coined by Jacob.
3. For a description of these compounds, see Shulgin, A. T. & A. Shulgin, PIHKAL, Berkeley, CA: Transform Press, 1991.

Different Kinds of Trips

There's the *psychedelic* trip and the *psychoactive* trip. The psychedelics are the acid, mescaline, psilocybin. Visions and hallucinations and things like that. That's what characterizes the psychedelics. These three are psychoactive, but there are other psychoactives that are not psychedelic - MDA, harmaline, and ibogaine. Some people see colors and some visions on those.

Harmaline
I would put that in the psychedelic one rather than just the psychoactive one without the psychedelic because we don't take it alone, nobody takes it alone. It takes a helluva lot to turn on and you get so God-damned sick if you took enough to turn on that it's horrible. We take it with acid or psilocybin and it puts a new dimension on the acid trip. Very primitive, you get right down to the primitive side of yourself. The men who take it find their real masculinity and the women who take it find their true femininity. As a matter of fact, some Indians when they take yagé and they have their religious ceremonies, the men take it separate in their own hogan, and the women take it separate in their own hogan. They do not mix, because for the women, it's a woman's medicine, and for the men it's a man's medicine. Same medicine.

Myron: On the psychoactive list, would you put MDMA on that list also?

Jacob: Yes. That's Adam. Right. It's not a hallucinogen. The hallucinogens give visions, colors, and new dimensions to all of the senses, like hearing, vision, music - you know, music is a trip - and that's for all three of those. Hallucinations are very characteristic of course with eyes closed or eyes open, it doesn't matter. That's what I meant when I said visions. In some ways, people will say that they have a more spiritual trip on the hallucinogens because they see very important visions, spiritual visions in some sense to them. It's all an individual experience and their own reaction to it. The most popular one for that is psilocybin. It's a more spiritual trip. People will say that, although they'll also say that it's a spiritual trip on mescaline and acid. Now we'll go to the others, like MDA.

Myron: Just before we leave that, there's another thing. I don't know if you've read much by Gerald Heard. He talks about analytical thinking versus integral thinking, and with the hallucinogens, and maybe this is what you're calling visions, too, somehow you seem to jump up to a higher level of understanding where things seem to fall into place and relatedness more clearly.

Jacob: Oh, yes. That happens definitely on the hallucinogenic trips. Very clearly. That's part of the transformation.

Myron: Higher conceptualization?

Jacob: Conceptualization - most people would object to that, because it's not a conceptual process.

Myron: Maybe realization.

Jacob: Realization. Experiencing in a new dimension. And, coming out of a very deep level of feeling. I prefer feeling to emotion, although emotions will accompany it. Crying and things. Again, the word that I would use now is a realization of the truth. THE TRUTH. God's truth. Not the one we think is truth. Not of the mind. It's of the Self. The soul. Everything you see that you experience you experience with a whole new configuration.

MDA
Psychoactive, very clear, answers questions, MDA clarifies your life, puts everything in a correct perspective for you, tells you what you are doing that is satisfying, what you can do that will be more satisfying. You come out with a good feeling about yourself. It helps you to see all your difficulties in a different light, and they cease to be difficulties. You become aware of the fact that everything is happening just exactly the way it should be happening, and you're doing everything you need to do. Just relax and go do it! This is pretty

characteristic, at least with the first trip with MDA. Subsequent ones, too. It's a great experience for relating people to each other - yeah - you have a good feeling about yourself and the world around you. It brings you into the experience of the moment. That's the greatest material for learning that lesson. There's nothing but the moment, and that experience brings it home *very well*.

I remember one trip that I had, every time that I'd get anxious the trip would tell me, "Everything is in this moment, nothing exists except this moment. There you are. This is what exists." Every time I would get anxious I would say, "Hey, wait a minute! I'm anxious! What was I thinking about just then?" What I was thinking about was before or after or about to or whatever. I wasn't in the moment. I said, "See, you're not here in the moment." I'd look around and I'd experience with my senses and the anxiety disappeared. It's a great lesson to have. That's MDA.

Ibogaine
Ibogaine is something else. It's similar. All of these have certain qualities that are common to all of them. Also, no hallucinations. It's a heavier trip. A deeper and a longer trip, and for many people it takes longer to turn on. It's a very profound trip for everybody but people experience it differently. Some people love it, they love the lessons that they get from it. Some people find it a very painful experience. Those who find it painful are the ones who have not been confronting what Mr. Ibogaine is handing them and have been trying to avoid it.

You asked me once before something about confronting blocks. This is a place where people will confront blocks, as a matter of fact, if they have been unwilling to accept them or believe them or often try to deny them. A truth that they're trying to deny. Mr. Ibogaine won't let you do that. You can fuck it up if you want to. But nobody wants to. You have a great respect for Mr. Ibogaine. You experience it. Great respect. You listen to it. You may not do anything about it but you'll know that this is true. This is so. Yeah.

MDMA
And then of course MDMA. *Beautiful* trip. Just full of beauty and love and good feeling and acceptance of your self and realization of your own perfection in such a way that you say, "I don't think I ever want to put myself down or find myself wrong, because I'm not wrong. I'm being guided all of the time." It brings that into an experience.

Dose Levels

Jacob: Nobody can come to the group trip until they've first had a trip with me. I've already established the level it takes for them to turn on with acid. All first trips are acid. Even if they've had 500 acid trips before that. Suppose they have a full trip on 250 micrograms. All right, then 250 is their dose level. It could be more. I generally start at 250 unless I have a reason to think that they're more sensitive and don't need that much.

Sometimes 250 isn't enough, I'll give them another 125 micrograms. If that isn't enough I'll give them another 125. I keep building it up gradually until they really are turned on.

They may have to have 500 to turn on. Some people have to go up to 750 to turn on. Hard heads, I call them. If they started out a t 250 and ended up with 500, I'll call their base level 375 micrograms, halfway between 250 and 500 because by the time I gave them the second booster they've already dissipated a certain amount, they don't need more. That's the base level, and the base level for acid in general becomes the thing that I compare all the others with.

When they come in for the group trip we talk and decide what they're going to take. They want to know what's available, what kind of trip it is, what happens on a trip. They don't know what to do because they haven't had any experience with it. I generally suggest a second one to try. They may want to have another acid trip or they want to have a psilocybin trip or something like that, because they've heard about it. We'll talk about it and we agree on a format, and I decide on the dosage they're going to have, because I have something to compare it with and they don't have.

Frequently now, more frequently than anything else, I suggest MDA for the second trip. I tell them, "It's a very different kind of trip. It's not like your other one was. It's also a very, very good trip for you." And they say, "Okay. I'll take your word for it."

If they take 250 micrograms of acid to turn on we start them on 150 milligrams of MDA. Most of the time that's enough. After an hour, if they're not turned on, I'll give a 50 milligram booster. Most of the times that'll turn them on. If it doesn't turn them on in thirty minutes I'll give another 50 milligram booster. On this trip they'll establish their base for MDA. There are variables between people, you know, and also variables with the same material with the same person from one time to another. But this is the general picture.

Okay, they've had that trip. Then they come in and want to try another, a different kind of material. I'll suggest either psilocybin, which is hallucinogenic, because a lot of them love the visions and things like that. Or mescaline. Ibogaine is much later. I like for them to have that after they've had the others. Ibogaine is about the last one I have them try. It's a progressive, one, ibogaine. Each trip brings you to another level.

Myron: How much psilocybin do you give?

Jacob: Three grams of the mushroom is equivalent to 250 micrograms of acid. If they took 375 micrograms of acid, we'd give them 4.5 grams of the mushroom.

Myron: It's a pretty direct correlation?

Jacob: Pretty direct. Yeah.

Myron: And how much mescaline would correlate to 250 micrograms of acid?

Jacob: Most people don't really turn on with less than 500 milligrams. We don't do mescaline very much because it's very expensive and they seem to get as much out of the acid or psilocybin as the mescaline. Nothing special comes to them on mescaline.

MDMA

The first time they take MDMA I give them 150 milligrams. Sometimes that does it for them. If it doesn't, then I give them a 50 booster. After that we establish their base. Then I know that it takes 200. The maximum I'll give is 300 although there's one person who takes 300 and a booster of 200 after he's started coming down. It doesn't hurt him. Doesn't hurt his heart or anything like that. I don't feel comfortable giving them more than 300. If they haven't turned on I say, "You take what you've got and that's it." And you know, when they find out they can't have a booster they lay down and the sons of bitches they turn on! (Much laughter.)

I've had quite a thing about this business of boosters. I've had lots of hassles about it, because they want to really blast through. Sometimes they'll get close but they can't get through and they want to blast through. They think more medicine will do it. I tell them this every time we have a session, "More is not better. Lay down and stay down. No wandering around, because as soon as you start to be functional you detract. You've got to get into your ego to be functional. Lay down and have your whole trip and when you're all the way down, really coming down, then you can get up and walk around. Or if you have to go to the bathroom one of us will help you go to the bathroom." Or something like that. That's very important.

Harmaline

Harmaline goes with either acid or psilocybin. I generally give them 125 milligrams. I used to give them 250 milligrams and they'd get pretty damned nauseated by it. The 125 milligrams is sufficient for them. This is a psychoactive material but it's not psychedelic, and this amount does not add to the base level. They would take their normal amount of acid and just add this which does not increase the activity of the other psychedelic. It's just an auxiliary, and brings a different dimension to it. Some people would prefer 250 milligrams instead of 125 milligrams of the harmaline. Those who have trouble with nausea take it anally.

Myron: You just put a capsule up their rectum?

Jacob: Yep! You just say, "Squat, find your asshole, put the capsule right up your asshole, shove it up as far as you can. Go like that." (Demonstrates.) That always gets a nice laugh.

Ibogaine

Myron: That leaves ibogaine, then.

Jacob: This we have to explore to find the right dose. If I'm not sure how much it takes to turn them on, then I give them three capsules. A capsule is 75 milligrams of ibogaine, the active ingredient. It's a half gram capsule, it's a pretty big capsule. But the active ingredient is 75 milligrams of ibogaine. I give them three. That's about 225 milligrams. If they don't turn on after an hour or hour and a half at the most, we give them a fourth one, and they'll turn on with that. Few of them need more than that. It's hard on the body, too. I don't want them to take more if they don't need it.

They've established their bases. If they didn't turn on with three then I know that four is necessary. Sometimes I give them four and it was much too much and they know it. I mean they had too much. It was the proper amount according to the way that I grade it but it was too much of this particular medicine for this particular person. Next time I'll give them three. Some people do two. Some people get a little trip on one. Very rare, but they do. A mild trip. That's the idea.

Myron: Don't some people want to start with one and work their way up?

Jacob: Not any more. I used to do that. I tried it a couple of times, it doesn't work. I start with three. If three's too much you go back to two the next time. If three isn't enough then you go to four this time and you start with four next time.

I have a record of what everybody's taken, and how many boosters and how long into the trip they had to have the booster. It helps me to determine what to do. They learn themselves what their schedule is.

Okay, that's it for materials and dosages and kinds of trips.

Outcomes

Myron : What we might talk about now is you've had this large number of people who have come to you and have had individual trips and group trips. Could we talk about some of the kinds of changes that you've seen in people as a result of this?

Jacob: You know that's a very difficult thing to do. The only thing I can do at the moment is to recall what they were like when they first came to me, and then to see them as they are now - beautiful loving friends of mine out there in the world doing great things. Really doing great things. All of them. And continuously on the path of further exploring and further searching. I always try everything that comes along. When something comes along that I try that is very fruitful to me and could be fruitful to my people, I let them know about it. And they go do it. If they find something that's really good they let me know about it, and I go do it.

Your question now: "Can you say what happened to them?" One of the first things that they learn to do is to take complete responsibility for themselves and their lives. This is something that we *all* keep working on *all the time*. More and more and more. No more blaming. No more attributing the cause of anything out there to anybody else. That's really the *heart of the whole training* that I'm involved in. You could describe it in one sentence, that's it.

There's many manifestations, many ways that you can go about it. The people change from a very disturbed, mixed-up state to a clear place where they function much more creatively, in terms of relations to themselves and outside. They affect the lives of everybody they come in contact with in a positive way for the most part, whereas before they affected them negatively. They gave them trouble. They are much more satisfied with themselves. And they are committed to the process, to the growth process, to continually exploring. This is true for most of the people I've worked with. Some have drifted off, I don't know what else to say. It's not their bag right now.

Myron: How about sensory enhancement?

Jacob: Yeah, our eyes become open! It's like the Garden of Eden. Our eyes become open, and our senses. We're much more aware, much more acutely aware. For food, that happens. Especially right after the trip. You fall back in your old ways all the time, too.

You're trying to find out whatever I've discovered about different kinds of outcomes from tripping. Transformation is the only word that will fit. From one way of looking at things to another one, whatever they're looking at. I always tell my people, it's one of my favorite statements: Nobody has ever been able to achieve transformation by their own unaided efforts. This is a belief that I have. It requires some sort of a medium. The medium can be a medicine, the medium can be alcohol, the medium can be transformation of consciousness. Could be a deep crisis in their lives. Could be a priest or a minister or a psychotherapist as the facilitator. It could be something that they smoked, it could be some one of thousands of things that grow that they would ingest that turn them on. Turning on is the phrase that I use now for getting into a state where transformation occurs.

But just by sitting there and trying to do it, I don't know if anybody else has done it. Even Milarepa. He did it by sitting for a number of years in a cave meditating. Sensory deprivation. I think that's the best word that we have that tells what happens on an LSD trip. They've taken blood samples from people who have been in that meditative state and from people in the middle of a trip and they find that the changes in the blood are very similar. The serotonin content of the blood and I don't know all about that chemical stuff. I'm not good on the chemical stuff. The same things, the same results come. The visions that they have.

Myron: I'm curious about the progression that people make with these different materials. First they start with LSD and then possibly when they join the group they'll repeat that or try psilocybin and then you recommend MDA...

Jacob: If they're doing all right we'll talk about the different materials and the kinds of trips they may choose or they may say, "I don't know, I don't have any basis for choosing." So we'll say, "Well, try this. This is usually the next one that people take."

Myron: And after MDA then maybe you'll have them try Adam.

Jacob: No. Another psychedelic with yagé. We try to get them through the spectrum of things as soon as we can so that they know which ones to choose.

Myron: Then after yagé maybe MDMA.

Jacob: Well, psilocybin. It may take a year or so before they've gone through the spectrum. There's also tripping at home, too; people will do that with other group members. They'll have a little group combine and have a trip with somebody sitting with them, so they have other chances to trip once they've been a member of the group.

Myron: Once they've been exposed to the whole spectrum, i s there any kind of weighting? What is the popularity distribution of the different things? Are there any particular favorites?

Jacob: Adam is definitely first, MDMA is first. It depends on where they're at and what kind of trip they want. If they haven't got anything special they may just want to have Adam again because it's such a beautiful trip. If they've got things they want to work on they'll take a psychedelic, or they'll take MDA or something like that. We don't use much MDA any more. A work trip is a yagé trip or an ibogaine trip where they've got things to work out.

Myron: Do you have any feelings about what each of these things are specifically best for? You did give me that.

Jacob: Mostly there is much more likenesses between them all than there is differences. They all turn you on, they all bring you back to your center.

Myron: I am a little surprised at your initial dose because that seems higher than what some people use as an introduction. I guess really what you're providing are very profound experiences and you're really pretty focused and oriented to make sure that they get the most profound kind of experience.

Jacob: Right. And it goes very smoothly, because it's a routine kind of thing. Yet it draws my attention, holds my energy, and all of that.

I really wasn't aware of how much energy went into this kind of thing until I stopped, really started cutting down. It took me two to three days to recuperate, because it takes one hell of a lot of energy out of a person.

Myron: I wanted to ask you, with individual sessions, too, do you find it tiring?

Jacob: Oh you, damned right! Absolutely. I don't schedule anything for the next day, as I'm very tired the next day. When I come home from the thing I just plop into bed. Even though I'm sitting still all the time! And I'm reading! You know, keeping my mind interested, but there's a draw of energy that's fabulous.

Myron: I thought it was the most tiring thing a person could do. I probably had problems where I was probably too involved, but I know our Medical Director quit sitting with people just as soon as he had others who would do it.

Jacob: I was very involved in the very beginning. Now I'm not that way involved.

Myron: Do you find that you're less tired?

Jacob: No. No. I'm still very tired.

Myron: It takes a lot of energy.

Jacob: Yes indeed. I'm still very tired. But I don't get emotionally involved with them. I don't cry when they're crying and when they experience something I don't identify with it. I just sit there quietly and I'm aware of what's going on and when they start to cry or when they're doing something that indicates where they're at in their trip I say, "That's great, oh, fine, stay with it, kid." Something like that.

Myron: It must be enormously satisfying. Even with the little bit of work that I have been involved in there's nothing more satisfying than when another person makes these discoveries.

Jacob: Right. It's what I said earlier, there's nothing more satisfying than turning somebody on to themselves. At the end of a weekend when I'd see what fantastic things have happened to these people, I'd say, "Whatever I've had to go through, it's worth it to produce these results!"

See Appendix I for examples of personal accounts.

Finale

It is now sixteen years since these interviews were conducted. Simply rereading them has brought back the richness of these encounters, and an immense appreciation of the expanded vistas that psychedelics make possible to the earnest explorer. They support and confirm a wealth of additional accounts given by other researchers[1].

Immersed in the impact of this work, it seems to me incomprehensible that our society has sunk so deeply into unconsciousness as to be unaware of such possibilities. The general public, unfamiliar with the power of our minds, remains for the most part locked in mass hypnotism, secured within the self-constructed walls that lock out the prodigious possibilities of life, the joy and exuberance waiting to be claimed. Our birthright of wisdom and compassion has been sacrificed on the altar of self-interest, materialism, and reductionism. So opposed are we to discovering the errors of our decisions that we have made practically all substances which can reveal to us our true nature illegal to possess.

Nothing would have pleased Jacob more than to know that the telling of his story has helped our society understand that there are powerful tools available for self realization - that vast new possibilities in life await us when we take on the responsibility of making these new tools available and learn how to use them. We will then recognize Jacob as a true pioneer and dedicated servant of humanity.

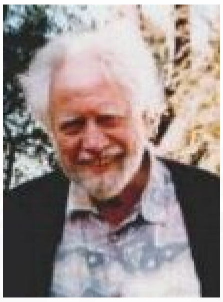
Epilogue

The Last Trip: Peaceful Closure for Jacobs



Sasha Shulgin

My first memories of Jacob were back in the early days of the Berkeley scene, during the time of the free speech vigor. No, my first meeting with him actually preceded all of that, and even preceded the Berkeley Barb being peddled by bearded hippies on every street corner all the way up Telegraph Avenue from Dwight Way to Sather Gate. As I remember, it even preceded the tear gas and the helicopters of law and order. Pre-People's Park. Pre-Doctor Hippocrates. Pre-Mario Savio. Jacob and I would agree to meet at our favorite cafe on the Avenue and share an espresso (a new fad just introduced from Italy) and discuss just how to get the pink color out of crystalline MDA. I had no idea, and had never asked, where the MDA had come from, nor why it was pink. Jacob never told me. But I suggested washing it with ether containing a bit of acetone, and the pink color apparently went away. This was in the pre-MDMA era, when MDA (the "Mellow Drug of America," sometimes called the "love drug") was very much the favorite of the therapists and the psychedelic explorers of the time. It had been kosherized, after all, by being promoted by one of the largest pharmaceutical houses in the United States (Smith, Kline and French) after having been discovered and espoused by an eminent Professor of Pharmacology (Dr. Gordon A. Alles, from UCLA).

I was not particularly interested in MDA, as I had my own acaulescent world of phenethylamine relatives that was going in all directions at once. And Jacob was not particularly interested in my manic and broad diffusion of new compounds as he had his MDA which was a familiar and, for him, completely predictable tool. A decade or two later, I caught his attention with the material MDMA, but that story is the stuff of a chapter in another book. I would, here, rather talk about quite a different material, mescaline. This remarkable alkaloid demands a special place in my notes as it was the first psychedelic I had ever tried. And, it commanded an equally special place in Jacob's notes, as it was the last of his experiences.

I, and a number of my friends, had found a time for communion and exploration, and mescaline was the chosen vehicle for the day. Jacob accepted 300 milligrams of the sulfate salt in water solution, wished us well, and drank it down. As did we all. In a half hour he retreated towards the bathroom (nausea is a rather dependable companion under such circumstances), then he chose to lie down by himself in a back bedroom. I searched him out in another hour, but he indicated that he wished to remain alone for a while yet.

An hour later he rejoined us, with a humorous yet wistful smile on his face, and told us that he had pretty much decided that this was it. He had had it. "Too much nausea?" I asked. "No," he replied. "It isn't until I have gotten sick and urped that I know I have turned on." "So what is this 'it' that you have had it with?" I asked him.

He sat down in a soft, comfy chair, and looked at me, and smiled. "I think that I have found my place of peace. I know that I will live until I die, and I don't have to rush it, and I don't have to keep proving that I still have piles of life left to explore. I'm getting too old to try to demonstrate to others that I'm young and still learning. So I'll just let things be. What's to prove?"

He sat there for the next couple of hours, watching all the others exchanging dynamic interplays of ideas, opinions and clever conversation. All this was not directed towards him, but was simply cast adrift in the air about him. He listened, and that infinitely peaceful smile never once left his face. I suddenly realized that some day I, too, would be an observer of the passing scene rather than a participant in it.

A few hours later, as we all sat around a fabulous chicken casserole with some acceptable white wine, I asked him if he had had a rewarding trip today. He told me he had, indeed, been "out there" for a while, and that now he was back with us he thought he would probably stay here, in this reality, for his remaining days. He had closed his circle. He was together.

I hope that someday I will experience the completion and the integration that I saw, that day, in Jacob's face. At that future moment, I just might discover that I too have become a complete person.

Appendix I

Personal Accounts

The results of the author's in-depth interviews with five different individuals who have gone through the program described in this book are summarized in these personal accounts. The information was mostly prompted by questions asked of the individual participants. Assumed names are assigned in each case.

A word about the questions. Those of a scientific mind would no doubt like to see the questionnaire that was used for these interviews. As a matter of fact, it was my intent to develop a questionnaire that could be filled out by all the participants, and I would summarize the results by analyzing the answers. Jacob objected very much to this, as did others who had extensive experience with persons going through this program. The problem is that these experiences are such expansive openers, and lead into so many dimensions of understanding and experience that it is quite restricting to attempt to channel the results into the narrow ruts of a preconceived set of questions. The attempt to do so is limiting and frustrating to the person being interviewed.

Consequently, I armed myself with a checklist to make sure I covered areas of interest, and at the same time encouraged the participant to relate what they found to be most interesting and valuable. In this way I hoped to capture important areas of functioning, while allowing the participant to communicate more fully the extent of her or his experience.

Robert

Robert is in his early forties, unmarried, and works as a commissioned salesman. He first became drawn to psychedelics through reading about them. After he participated in his first psychedelic session, he continued with one experience per month for eleven months. By the time of this interview he had completed seventy-five to eighty psychedelic sessions, ten of these on his own. The compounds which he has experienced include MDMA, ibogaine, LSD, LSD with harmaline, peyote, mushrooms, MDA, and 2C-B[1].

When Robert became aware of a program that used psychedelics therapeutically, he entered it. His sense of adventure played a part in motivating him to participate. He was also motivated by his yearning for an experience of God, feeling that this was an important aspect of life that he was missing. In addition, there were a number of things about himself that he was not happy with and that he hoped to change through the therapeutic use of psychedelics.

In Robert's first session, he ingested three grams of mushrooms. He felt his female companion became a leopard woman. When they reached out and touched, red energy passed between their hands like a neon light. Later in the afternoon he found that everything was gorgeous. His first group experience was with ibogaine, where he had very rich and enjoyable interior visions for many hours.

During a memorable experience in which he took a combination of LSD and harmaline, Robert found the power within himself to feel his strength and explore his masculinity. He found himself to be fearless and a powerhouse of energy. During this session Robert felt strong like a leopard and was able to overcome his fear of snakes.

After his second most significant session, a powerful experience with 2C-B, he felt that he had "cleansed his lenses"; the world looked different, like washing a muddy car. A heightened sensory awareness stayed with him after this session, and opened him up to and was extended by a subsequent MDMA session.

Robert describes an experience with MDMA as his most profound psychedelic session. The session began with the ingestion of 150 milligrams of MDMA. After one and a half hours he had not noticed any effects so he ingested 75 more milligrams as a booster. This first booster did not achieve the desired effect so a second booster of 50 milligrams was reluctantly administered. Even after being administered a second booster his experience had not started. Robert asked for another booster but his request was denied. He was told perhaps it was about time that he had a nothing trip. Three hours after the beginning of the session he had a profound experience of God which he describes as the most joyous moment of his life. A month later he was still happy, joyous, grateful, and completely satisfied.

Robert attributes many of the positive changes in his life to his psychedelic therapy. Of the benefits he reported, the most outstanding has been that of profoundly experiencing God within himself. Before he had these psychedelic experiences, Robert had rejected Christianity and had no feeling for the existence of God. He has since joined the Unity Church and attends services, which have become the highlight of his week. He is now engrossed in reading spiritual books, listening to music, looking at nature, with gratitude at the beauty of the world welling out to God every day. He has not undertaken any new formal education, but has greatly increased his reading and study through the Unity Church.

The overall quality of the relationships in Robert's life has improved. He now feels more relaxed around people, more in the present. He has dropped some of his shyness, and is less clinging. He has discovered that he essentially loves his mother, whom he had felt was a very difficult person. His experiences have allowed him to keep relationships going despite resentments. He feels an ability to experience love, which he had not done for years.

When dealing with the world at large, Robert no longer feels the need to be constantly on the lookout, scanning for danger. The fear of danger has now fallen away. His fear of death and anxiety levels have also diminished.

There has been a significant change in Robert's relationship to his work. He has dropped an old, stressful job and has taken a job based on commission. Previously he was much too rigid and anxious to consider a job where income was uncertain.

Robert has also experienced a change in his recreational activities due to his psychedelic therapy sessions. His appreciation of nature and his love of music have increased. He has abandoned his television set, acquired a huge record collection, and reports a greater interest in reading, particularly metaphysical books. After sessions, he often has spontaneous flows of writing.

The detrimental effects that Robert has experienced have been occasional feelings of paranoia. One of these experiences began with a group session in which he had taken a peyote extract and mushrooms. The initial dose did not achieve the desired effects so Robert took a booster. The first part of the experience was pleasant, but in the afternoon he turned quite paranoid. This feeling lasted for a week, until a solo experience with MDMA erased it.

Robert had another bout with paranoia when he ingested 100 micrograms of LSD with a friend. In this instance, talking it through with his friend cleared about eighty percent of his paranoid feelings. Robert also experienced paranoid feelings for a period of close to three months after his 2C-B encounter; however, he felt that this experience laid the groundwork for his magnificent MDMA journey. On another note, though his intuition has increased somewhat and there are times at work when he gets a sudden flash of understanding, his energy level has gone downhill. He finds it hard to get started in the morning. This is sometimes disturbing. He thinks it may be aging.

Overall, Robert reported a great improvement in the quality of his life because of his psychedelic therapy sessions. All of his experiences have contributed to this, but the MDMA experience was the most outstanding, with the 2C-B experience next. He can better appreciate the beauty in the world and God plays an important role in his life. One of the greatest gains is the contact with the group, sharing experiences. These relations are now the richest part of his life. Through his psychedelic therapy sessions Robert has gained innumerable insights about himself and the world in which he lives.

Susan

Susan is 34 and a freelance graphic artist. When she learned of the program of psychedelic therapy, she immediately wished to participate (3-1/2 years previous to this interview). She has had approximately 40 experiences, about half of which were on her own. She has used LSD, LSD and harmaline, MDA, MDMA, ibogaine, mescaline, 2C-B, and mushrooms. She entered this program looking for a booster in life and to further develop the progress made through another personal growth program.

Susan has had a number of outstanding experiences with psychedelics. Some very dramatic ones have occurred with ibogaine, her favorite material. She finds that ibogaine forces you to look at what you have placed between yourself and love and that you have no choice; it will not let go of you until you are redeemed. Many people do not like it but she finds that the best thing to do is "confront your crap rather than laying around in paradise." She always feels best after experiences in which she has confronted fear.

Before one ibogaine experience, Susan had set herself up for a perfect boyfriend where she would function out of love with no projections.

She took up with the boyfriend of her best girlfriend after the two broke up. Her girlfriend returned after thirty days and reunited with her old boyfriend, which hurt Susan very deeply. She took ibogaine and went through cycles of resentment, fear, anger and sadness for hours and hours, over and over again. It wouldn't stop. At the end of the day she sat up and decided that at least she could get up and go to the bathroom. She suddenly experienced her head filled with light. For the next half hour she felt like the Buddha, a most beautiful experience. Her conclusion is that Mr. Ibogaine does not let go of you until he is through with you.

During another ibogaine session, she thought knives were hidden everywhere and she was filled with murderous thoughts. She saw Jesus being crucified and finally drove in the nails herself. After hours and hours of experiencing Christ crucified, she realized that Jesus forgave her despite her abominable act, and that He also forgave Judas. She then reached a sense of Cosmic Consciousness, One Mind and the knowledge that God was real.

At another time she took MDMA and had a glowing experience. A week later with ibogaine, she asked why life could not be like the MDMA experience all the time. The answer came quickly, "Because of fear." She thought she now had the answer and was through, but a voice said to her, "No you don't!" She was then forced to experience fear in every conceivable way. She kept trying to hide but was unable to, so she finally gave up. The experience was horrible, with much yelling. She described the most comfortable she could feel was to have one million razor blades stuck into her body and have them explode. She saw no hope and finally gave up and collapsed on a pad. She was then filled with a channel of white light and felt reborn. Beauty came, and there was pure, exquisite tension between fear and beauty. She did one of her best designs after this experience.

In her personal growth pursuits, Susan felt her biggest decision was to stop making herself miserable. Before, her energy was hyper and frantic and she felt she wasn't "home." Now she realizes that she can be still, rather than constantly chasing after activities. She is willing to make peace with the past, allow herself to feel depressed sometimes, and look inside herself for her real intention.

The biggest benefit of Susan's psychedelic therapy has been freeing herself of projections. She used to project onto everything. In her relationships, she would fall in love, project all over her partner, and drive herself crazy. She has since learned to ask herself what she really wants and has discovered that love is not "out there" to be found, but comes from within yourself; you don't need to go running after it.

Interestingly, Susan reports that she stopped wearing glasses. She feels that she doesn't need them because her vision has improved. She is more aware of detail and color and is less distracted. She can become absorbed in the beauty of simple things, like the reflection of lights from waves on the surface of water.

In the area of sensitivity, she finds herself more open, not as defensive, and has dropped fears and judgements. It is much easier for her to make close contact with people in everyday affairs such as clerks in stores.

In terms of her creativity, Susan reports that her graphics have gotten "very clean in design." She finds that after confronting her fears in experiences she does her best designs. A significant change took place in her work activity. She was a supervisor for a while, and went through a period of attempting to make her department very efficient, eliminate sloppiness, "get on the ball." She wanted to run things in a regimented manner, but no one was interested. In pondering the problem, it came to her to attempt not so much to control her coworkers but to relax her stranglehold on them and trust the process. In finally deciding to "let them do what they want," relations immediately improved, the employees were happier, and things operated more efficiently.

Susan had been very resentful of her mother and father, despite having been given everything. She previously saw herself as a "snotty little kid" resenting authority and wanting to grow up immediately. In her first psychedelic session she realized the contribution her parents had made to her life, and totally flipped in her attitude. She forgave them even though there was nothing to forgive, and the relationship has been wonderful ever since. In addition to the renewed relationship with her parents and the continued easy, open relationship with her three sisters, she now has a whole new set of friends, mostly those from the group psychedelic experiences, who now feel closer than her own family.

The biggest change in her life regarding her conduct with other people has been learning to mind her own business. She has found it best not to sympathize or empathize with others to help them get over hurts, but simply to tell the truth and mind her own business. This is working very well.

Susan at first had a strong feeling that she had to help save the world. Despite volunteering eight hours a day on top of an eight hour job, she was compulsive and felt guilty that she was not doing enough. She now feels that whatever you do makes a difference; what is important is how you do it rather than what you do. She feels that working on herself is making a contribution to the planet. Since all minds are one, one day there will be enough clear minds to achieve a mass world improvement.

Susan has had some incredible experiences of God, or the One Mind of Cosmic Consciousness. Susan found that her own energy was insignificant compared to that of God. She learned that if she was stuck in an experience and was thrashing around, the answer was not to go looking for God but to realize that God is inside and to come from God. She has had some profound biblical-type experiences. The implications of these experiences for herself are to remove her own barriers and make decisions, take responsibility for herself, tell the truth as far as she knows it, and to understand that being willing is what frees one.

The only detrimental effect that Susan reported is that sometimes she would be tired for a couple of days after a session. There have been no long-range adverse effects.

Dick

Dick is 33 and has been married nine years. He owns and operates a stained glass business with his wife and another woman as partners. He had used psychedelics previously to entering this program, but mostly for recreation. His experiences were meaningless, had no direction, and he got nothing from them. Dick had about ten experiences before entering the program and has had ten to twelve experiences subsequently, starting about one year before this interview. Going through a non-drug personal growth program had opened a crack in his structure, and his psychedelic sessions have been a wedge to push him through to greater openness. He has used ibogaine, mushrooms, harmaline, LSD, and MDMA.

In his first solo experience, Dick broke down a lot of resistance and got in touch with a deepened sense of love for others. This has led him to no longer discriminate against people. He now realizes how important it is to have a support system. He has found that he is no longer interested in giving unsubstantiated opinions, but needs facts. Otherwise, communication is a waste of time. Before he loved picking holes in other people's positions, and considered himself a real "shit stirrer," which made people around him uncomfortable. He was a master of finding errors; one slip and they were dead. Since he is less preoccupied with himself, he can see others better, which has opened up relationships in many ways.

Dick's experiences in the psychedelic program have contributed to the cleaning up of specific areas of his life. In one experience, he wrote a letter to his deceased father and feels that his relation to his father is now complete. There is a break in his relationship to his mother - they cannot talk because of her attitude - but he has dropped the resentment from his side and has written her a letter of complete validation. He would be in instant ecstasy if she would call him. He has made it his intention to be back in a relationship with his mother in two months and to have an excellent relationship in six months. However, he is willing to have it the way that she wants it.

His relationship with his wife is now magnificent. Having experiences together has broken down the barriers between them and has allowed him to see his deep commitment to her. Communication has been opened up and he now gets tremendous support from her. They can work things out between them and let each other have their own being and their own space, which includes space for good fights. They can no longer get away with crap and find it easier to just tell the truth and act.

The most satisfying benefit has been to discover that "he is not bullshitting any more." These experiences have snapped his resistances and have had a total effect on all of his reactions. He has had powerful experiences of himself and other people and now responds out of who he is. Discussing specific changes, in the area of awareness Dick feels that he is clearer, more willing and more open. He is much more aware of other people and their names and is more willing to be supported by them.

He has also had profound experiences of God which have increased his sense of connectedness to others and all things. He has found God and lost his fear of death. Dick was always aware o f nature, but in his first experiences he was able to notice just how aware he was. He always saw the detail but now he sees God everywhere. He has become less destructive to the environment and has cut out using pesticides. Gardening and mowing the lawn are jobs that are a thrill to do. He makes time for them even when he is pressed.

In the religious area, he used to think that the Catholic Church was God, and had gone to seminary. He has found God and his connectedness to the rest of reality in his psychedelic experiences.

He reported that during one ibogaine experience, he was scared shitless. He left it in God's hands and was willing to feel whatever emotions were coming up. He has symbolically died twice during experiences. The result was loss of all fear of death.

Since beginning the psychedelic sessions, he has gone to glass school and a communication workshop and has signed up for the Course in Miracles. He has made a commitment to run in next year's marathon. He had previously considered that running any distance was ridiculous and used to make fun of his wife for running. He now finds that when he gets tired running, he can pull energy in through the palms of his hands. It is almost like having a session.

Dick has always been energetic, but he now finds that he wastes less energy. He has eliminated fretting, finding it easier to start producing results rather than fret over problems. He is more willing to confront failure, which releases energy for positive action. He is better able to focus energy and has discovered how useful it is when working with other people to have them all sit down and focus their energy together. Otherwise there is a tendency to act from an unconscious place which dissipates energy and life and is not as satisfying. If things are left to fate, one remains unconscious.

He and his partners, who are also in the psychedelic program, now have more significant relations with their clients and feel that they make a difference in people's lives. They have endeavored to clear out all unconsciousness from their business operations, getting together to go over the operation and plan the work. They have hired a consultant, changed the name of the business, studied the market, and reviewed all aspects of the operation in order to carefully choose their direction. Finally, they have shifted the context of their business from profit making to being a source for their favorite charity. This was scary at first, as it was hard to ask people for donations and risk losing their business.

With regard to creativity, Dick is now aware that he can be the creator. He is willing to let go of the past and has more facility producing new, different designs and having them be exactly what he wants. He can stay with an idea and keep working until it is just right. The improved focus on creative work has lead to an award-winning design. Clients are now ordering larger pieces, worth two to three thousand dollars.

Dick has had to learn how to get free of his own thoughts and the thoughts of others and address the person and the context. He has found that focusing on reality creates realities. He can change reality instantly by confronting the context and not what people think about it. This leads to very positive results and is freeing and ecstatic. This approach can be used anywhere to plough through the junk in life. In a personal growth program, he learned to understand the concept of coming from context rather than content, but he found that he had to experience it before he could use it. Now by owning the project, he can make it work.

Mentally, he has experienced the meaning of larger contexts, which has been freeing and ecstatic. Formerly, he was unable to imagine a context larger than himself. He can also experience the power of operating from a larger context.

Dick has testified that he finds it extremely important to plan his experience ahead of time and know what he wants. He feels it is very important to have psychedelic experiences together with those to whom you are close. In such cases, it is good to share with the others ahead of time what you wish to get out of the experience. Having a psychedelic experience is a tool to be used when it is necessary. It is not a good enough purpose to just go along: One must be clear upon entering, and use the experience as a tool. He is confident that what happens depends on the way that you enter and how willing you are to have it the way that you want. He has found that it is difficult to have it very, very good, and this is sometimes harder than dealing with a problem. He also found that if he didn't want problems during an experience, he didn't have to have them.

Detrimental effects occur mostly when he is coming down from experiences. He usually goes through a period of agitation when the chemical is wearing off. Also, he doesn't like to go to work the next day.

Carol

Carol, 36 years old, started her professional career as a teacher, but dropped this to work in administration at a university. During her psychedelic program she decided to go to graduate school and study psychology. She had a job in research, followed by an internship in which she counseled people. She ultimately returned to working with children, where she could combine her training in both education and psychology. She is now in private practice, specializing in working with youngsters.

Carol started therapy with Jacob at age 23, participating in a Gestalt Therapy group. She had no previous experience with psychedelics. She was unhappy with herself and was impressed by what some of the other members of the group had t o say about their psychedelic experiences. She admired and respected the other members of the group. From their commentaries, she thought a psychedelic experience might be a good tool for her to get in touch with herself. She has since had around 50 experiences over a period of 13 years, about one half of which were on her own with friends.

She has tried just about everything: LSD, ibogaine, mushrooms, MDA, MDMA, mescaline, peyote extract, TMA-2[2], harmaline and ketamine. Her favorite material has been ibogaine, followed by MDMA. Beyond these, the choice depends on her mood. While psychedelics have opened her up, she feels that she has also benefited from other personal growth programs, meditation, and healthy eating.

One of Carol's most memorable experiences was a very heavy trip with harmaline during the time that she had been studying behaviorism in school. She imagined herself walking down a one way street like a movie set, acting out behavior that wasn't appropriate. At the end of the one way street was a bucket, and she would throw up in the bucket. As she experienced this in her mental imagery, she would actually throw up. The whole scene - visually, kinesthetically, the whole situation of behavior - would end up with her throwing up into the bucket. Then after a while she would be on same street again doing a different behavior, feeling it all out and throwing up. A whole series of inappropriate behavior ended in her throwing up this way. This was a very strong lesson in her kinds of behavior, where they were getting her, and where the pain and suffering came from.

A bucket and a box of kleenex used to be important adjuncts to her psychedelic journeys, but not so much any more. Either she has cleaned out her stuff or found a different way of operating.

Carol has opened up to her own feelings and is better able to feel them, even though they may not necessarily be pleasant.

During psychedelic journeys, feelings are sometimes unpleasant, even painful. In a supportive, encouraging situation, she is able to feel these difficult emotions and ultimately accept them, which makes her more sensitive to the feelings of others. She now knows that the emotional discomfort will pass and afterward she will feel more energetic, more connected, and there will always be some benefit. She finds real value in facing fear and believes there is no rational reason for fear. She feels the fear when confronting it, getting down to it. Then it comes to the surface. She no longer resists it but finds she is freed from it. Having been through the fear, she can move on.

Before this program, she didn't get along well with either parent or her older brother. Now she gets along well with all three. All the areas of growth activity, including graduate school, contributed to improving these relationships. Her psychedelic experiences had a strong influence on these changes.

Carol reports being more connected to nature. This derives both from psychedelics and meditation. She finds much similarity between the two. She often meditates when on psychedelic journeys, and has psychedelic-like experiences when meditating. Her fiancé teaches insight meditation, where one watches one's breathing and anything that comes up. This enhances awareness and introspection, leads to compassion, and helps gain insights into connections with the world. It is based on Buddhism. One notices how everything changes. Most days she spends an hour a day meditating. She has experienced a very intense three month meditation retreat with 100 people where there was no talking.

She has an improved ability to get her attention off of herself; this frees a lot of energy tied up in fruitless energy loops. She feels she has gotten past her mind and has cut through a lot of verbal dialogue and chatter. She has a deeper sense of what's going on. She finds herself more centered, more grounded.

Earlier in her life, Carol wanted to get married, and wondered if she ever would. Then came a period of not wanting to get married and thinking that she never would. This was followed by once more wanting to marry, and now she is getting married to a man with whom she shares psychedelic experiences. Psychedelic sessions definitely helped to sort things out, cut through arguments and create the space to be open to communicate and hear what each other has to say.

Prior to meeting her fiancé, her psychedelic experiences helped her to get clear on who she is and who she wants to be with, how she wants to act, and what kind of behavior is appropriate. Her relations with friends have improved considerably. Some of her best and closest friends are in the psychedelic group and they share their experiences. A number of times when there has been trouble, a shared journey clears up what's going on. It permits Carol to put herself in the other person's shoes and helps her become more compassionate. Two days later she can often see the other person in a totally different space in the relationship. She doesn't necessarily need to talk about what the problem was. She feels this is a big area where psychedelics have helped her to relate more easily to people.

Carol feels she has become more forgiving and doesn't beat herself up as much. She hesitates on this point because before her psychedelic program she was politically more active. She wonders if she's become less ambitious or driven. However, she observes that before her activities were more like racing her motor; now she feels that what she is contributing is more rewarding and fulfilling. As a college student, she was in the streets, sitting in at gatherings. Her psychedelic experiences started after she finished college. Now she is much less politically active. She still volunteers at a local school six hours a week as community service. She now wants more sense of satisfaction from her volunteer work and prefers to be one-on-one rather than work in a large organization. She enjoyed being in an antinuclear march recently and contributes large sums of money to her favorite charity. She is presently forming a community for meditators which will be a retreat center, which she feels will be a positive contribution to the world.

Carol feels she has become aware of barriers, obstacles, and things that she does to sabotage her own energy. Her psychedelic experiences connect her more with what she really wants and where she's really going; she is more in touch with her priorities, and doesn't waste as much time. This is more fulfilling, and raises her energy level.

She noted several changes in her work attitude. Previously she was more afraid; she felt she had to do certain jobs or be fired and be out in the cold. Now she is more creative, competent, and not so self-pressured. Her career goal changed several times. She is now more accepting of change, and doesn't need a single lifetime goal. Goals drop or change; she is more fluid. These changes have covered some 20 years.

Carol finds herself more perceptive, feeling that she has less t o guard against. She is more willing to see herself in others, less judgmental, "better able to see what's going on," and more compassionate. Since compassion leads to higher awareness, she doesn't have to struggle against what she sees. This makes her more accepting and aware. Sometimes this is painful if there is a time lag between becoming aware of something she is not happy with and accepting it. A consequence of these shifts in her awareness is that she feels more confident, more at ease and more trusting, which allows her to put more energy into doing than wondering how she'll do it.

Carol reports feeling a lot more alive. She thinks she looks younger. She feels younger, less dragged out, healthier, and more spontaneous. She feels that her intuition is much stronger. She trusts her intuition more and it has developed and grown. She has much more creativity, again because she trusts herself more, and is more relaxed when looking at situations.

Carol's quality of life has improved immensely. Before psychedelics, she had no sense of fulfillment. She is happy that this has reversed. She participates in more recreational activities, enjoys them more, and does more of what she likes to do. She is more efficient in doing what chores and housework need to be done to make life pleasurable and satisfying. She is more careful about diet, and gains satisfaction from exercise. Psychedelic experiences are sometimes recreational, but this she can't count on.

Carol describes two effects that could be considered harmful. The first is that her memory is sometimes a little shaky. This might be due to a lot of marijuana smoking; she has also consumed a lot of alcohol. She sometimes wonders if there is any correlation between memory loss and taking psychedelics. She has cut back more on alcohol and marijuana than on psychedelics. The other adverse effect was that she recently got a bad kidney infection after an experience with MDMA. She probably picked this up when she was in Asia, but she felt that the MDMA experience may have lowered her resistance and permitted the kidney infection to manifest. She feels that in general, MDMA is not good for the body.

In conclusion, Carol was at first alienated from God or the spiritual. She felt unhappy and had psychological problems. She hoped she might be helped and was open to trying. Her psychedelic program was a long transition for her. She gradually let down and extended her boundaries. At first she felt tremendously isolated and alone. She had friends but was not really connected with other people. She no longer feels that she ends with her physical body, but is much more connected to the world; first with friends, then objects of nature, then more and more with the whole world. It is still hard for her to use the word God. It is not intrinsic to her vocabulary. She's a Buddhist and is very trusting of the process.

Carol feels the most important aspect in the use of psychedelics is the group context that she has experienced. The person leading the group, its structure and the attitude of the participants are more important than the use of the substances. It's about people not seeking quick thrills but earnestly searching for greater spiritual or personal growth.

Sally

Sally is 29 years old and is married to Dick. She is a partner with him and another woman in a stained glass business. She also does some work in massage. She has been in the psychedelic therapy program with Jacob for about one year, and has had ten to twelve experiences over this time. The psychedelics she has used include LSD, ibogaine, mushrooms, and MDMA.

Sally discovered in her first experience that life is about expressing what she calls the Real Self, a concept which she had not previously explored. After her first trip alone, it was very evident to her that there was a Spirit, an entity higher than herself that was part of her. She has found the psychedelic sessions helped her to cut through the layers of unconsciousness that keep her from realizing her true nature. This newfound ability has allowed Sally to progress in her personal growth at a rate that she never before thought possible. Problems and situations arise rapidly and are quickly resolved.

Most of her life Sally had beat herself up, been unforgiving of her own limitations. After some very uncomfortable experiences, she has learned to no longer do that. On her first trip with MDMA, at 75 mg., she felt she was wrung completely out and that elephants ran all over her body. On this experience she went through all of her fears. She meditated for five hours in the bathroom; she had never felt so horrible in her whole life. It was terrible. She determined that she would never again put herself through such torture. Since then she has had no physical discomfort when doing MDMA; perhaps on occasion a little nausea.

Sally's relationships with other people have changed since she began her sessions with Jacob. Her relationship with her family has improved tremendously. She is now much closer to her family than she has ever been. This started with her very first experience. Everyone in the family has come to understand that even when problems do arise that it does not affect the feeling of love that they share for one another. This deepening of connectedness can be seen in Sally's relationship to her sister. She always got along fine with her sister, but they did not communicate with each other very often. The relationship was nonchalant. After starting the psychedelic program, she began to talk to her sister more often, and the relationship deepened. They still don't see other often, but they are now very loving.

She describes her marriage relationship now as magnificent. She and Dick have been married nine years. They are deeply committed to each other, and hold their intention to maintain the relationship even when they are fighting. Before beginning the program there were issues in the marriage that she could not acknowledge or break through. But the psychedelic experiences permitted breaking through them, even exploding through. An ibogaine experience that Sally and Dick shared particularly illustrates this point. This session blew the lid off of the relationship. It came to their attention they were not being truthful about a lot of things in their lives. They took a good look at their commitment to each other, and felt very committed despite their old issues that were resurfacing. They found it was very important to have the experience together, as it created a safe space for complete sharing and open, honest communication.

Sally's professional life has also seen improvement from her involvement in Jacob's psychedelic program. Sally, Dick and their partner hired a business consultant and installed better management systems. They are committed to cleaning up unconsciousness in their operation and improving communication. The quality of their glass work and the panels they produce has substantially improved. She also notices a difference in the way she massages people. She used to work intently. Now she works more slowly and feels it is much more healing. She puts herself in the place of being God, just as in a psychedelic journey. She feels that by doing this it allows her to connect more fully with her clients and their particular needs. The change is wonderful. She feels that miracles really happen with people on the massage table. Sally now views her massage work as a means to communicate with the higher Self and to contribute to the healing of her clients, whereas before her psychedelic experiences she was just working with people's muscles. Sally states that she now has more energy, a stronger ability to focus, and greater healing ability. She claims that there is no comparison between the way these things used to be and the way they are now. She is absolutely clear that she can heal, not by doing the healing but by being a conduit for healing.

With regard to chores like housekeeping, Sally feels that giving service is a fulfilling pursuit. It's a way of being responsible for life, and being a source for relationship. Sally now sponsors two children in a ten day course for 80 youths at risk. These are kids who could go one way or another in their life. Her sponsorship is a lifelong commitment. This comes out of directly wanting to help keep their hope alive.

Concerning attitudes toward social issues, Sally had been exposed to the difference between content and context in EST (Earhart Seminar Training). However, this difference was not really comprehended until she started her psychedelic program, which has made it much easier to distinguish between the two. Now she can readily transcend chitchat into the bigger picture.

Sally once had doubts that she could create new life. In one of her sessions, she experienced life fully. She knows that life is about now, and that she is responsible for life. The feeling was like giving birth. Now she knows she can create new life. A crucial part of this experience was seeing Dick's mother, and realizing she could make life now. For Sally, part of choosing life is having children, and she knew that Dick's mom will live in her children. She was willing to make life right for her mother-in-law so that she can continue to live on in her grandchildren. Sally's willingness will help bring it about.

Sally has come to realize more fully the importance of continually participating in the world around her, to keep expanding her realm of experience. She has sought out more personal growth workshops and has sought to develop neglected parts of her life. One such development is that Sally has started singing again. She used to sing when she was quite young but as she grew through puberty into adulthood her ability was covered up with uncertainty and fear, and she could no longer do it. On one of her journeys she was very moved upon hearing a classical version of "Danny Boy." She discovered then that she really likes singing. She saw the whole universe laid out before her, and that she could do anything she wanted. When she asked what she should do, God replied, "Sing." She started taking singing lessons. Her husband reported that her voice has changed; it has expanded and opened up and has a much better sound quality. One interesting incident during an experience occurred when she was singing; she noticed that insects landed on her. When she stopped singing, they flew off. She has no explanation, but has good retention of the event.

Through her psychedelic experiences, Sally has become more of a spiritual person. After her first trip alone, it was very evident to her that there was a Spirit, an entity higher than herself and that was part of her. She finds that love is communication with God. Once Sally had accepted this notion into her life

she experienced an immense respect for everyone in her life. Sally finds ibogaine has the most lasting effect of all the substances: It "really hangs in there," and it provides much material to evaluate and gain insight from. On her last ibogaine experience, it took her seven days to reenter her previous state of consciousness. She became quite shaky by days four and five, and was very upset. Then all of a sudden she was completely back into life again. Overall, it was an excellent experience in which she saw that everyone is connected to Spirit. This connection was illustrated during the session by the image of a flame. Now when she talks to people she directly addresses the light or spark which resides within us all. Knowing this has allowed Sally to better understand and more effectively communicate in her dealings with people.

When asked if she has experienced any detrimental effects, Sally says that it often seems like she had difficulties when she was in the middle of a journey, or even a couple of days afterward. But when the experience is complete she always knows that it was very valuable. There have been no detrimental bodily effects.

Sally now knows that there's a Universal Mind out there. It never stops generating; it's an endless creating machine. One can learn to participate in the process.

1. 4-Bromo-2,5-Dimethoxyphenethylamine, a new chemical that was investigated for a while, then abandoned because of the variability in response and the fact that it did not lend itself.
2. For a description of these compounds, see Shulgin, A.T. & A. Shulgin, PIHKAL, Berkeley.

Appendix II: New to the Second Edition

Tributes to Leo Zeff

Sara Zeff

Sara Zeff - A daughter's tribute Spring 2003
I knew as a youngster that my father was involved in extraordinary and unique work. As I grew into my teens, he shared more of the specifics of the work and the need for keeping it quiet. He also offered me the opportunity to experience the world of hallucinogens whenever I felt I was ready.

At about the age of 18 he and I both decided the time had come for me to know, first-hand, the wonders of the psychedelic realm to which he was devoting much of his life. And so I was inaugurated into the inner sanctum of his world. I met and became friends with many of the people with whom he worked. They were all very committed to using these substances in thoughtful, therapeutic ways, yet most of them also delighted in the joy and fun the experiences offered. Leo increasingly surrounded himself with others who were dedicated to the work, people with whom he could share anecdotes and personal notes from their own trips or the trips of others.

As an adult, my life diverged from my father's, yet we remained close and he continued to share with me the work he was doing and the people he helped - the people whose hearts were so open after a trip that their worlds were forever altered in ways no talk-therapy could ever have achieved. Here are some of the more remarkable stories I remember. (The names have been changed.)

One of the first stories he told me was that of Chandler, a 60-year old man whose body was riddled with cancer. In 1965 there was only a primitive kind of chemotherapy available and after everything possible had been done, they sent him home to die. Being already part of Leo's "family," he was able to spend many weekends with the group he loved, tripping and opening his heart. In one of his post-diagnosis trips he experienced his own death. This is not an unusual phenomenon with hallucinogens, but for someone staring death in the face, it must have delivered a considerable emotional punch. In the aftermath, the group lovingly helped him go deeper into the experience by planning and carrying out his (mock) funeral.

The epilogue to the story of Chandler is that he didn't die of this cancer. The tumors disappeared. His is one of a handful of miraculous cancer turnaround stories that medical science cannot explain. At the time, the dumbfounded Chandler, his biological family, and Leo's family speculated that it had something to do with the psychedelics. It may have - or not - and he lived to enjoy many more years with a very open heart.

Somewhat less dramatic than Chandler, yet life-changing, was Benjamin. Ben was a homely, shy Jewish man in his late 40s when he began traditional talk therapy with Leo in the early 1950s. He had been born with a deformed leg, which gave him a nasty limp and an ongoing level of pain that was worsening as his muscles got older and stiffer. Ben was an elementary school teacher. He had no surviving family, a very poor self-image, never married, and his only sexual experiences had been with prostitutes. His students disliked him and ridiculed him behind his back, making his job very unpleasant. He was, in Leo's words, a miserable, joyless man.

By 1966, Ben had been in therapy with Leo for almost ten years, without so much as a modest breakthrough. For Ben, "Dr. Zeff" was someone he could talk to; not much else happened. As Leo gained confidence in the administration of the substances (then primarily LSD), he began to consider Ben for a trip. He talked to him about it and Ben, now in his 50s, agreed that it might be worth a try.

In his very first trip Ben broke through years of misery, cried for the first time in decades, and shared a hug - also his first - with Leo.

By the time I was inaugurated into "the family" and met Ben, he had been a member for many years. Although he was still in some pain and presented himself as a cautious, serious man, he was also quick with a hug and a smile. The group truly was his family, the only one he had ever known, and he joined them once a month to trip and to open his heart.

My father was passionate in his zeal for helping people overcome addiction. In the late 1960s, Leo and other practitioners began to discover that some of the substances held great hope as cures for addiction. That news traveled fast and Leo's friends and colleagues began a steady stream of referrals of alcoholics and drug addicts.

Some of the referrals could not pass Leo's rigorous screening and therefore could not participate in the work. But there were many who did pass and one of them was Peri. Peri had tried to kick her alcohol habit many times, but always returned to it when life got rough. Leo agreed to give Peri a trip. Through it she experienced feelings that she had previously deadened with liquor. Over time, with Leo's help, Peri took many trips and learned to accept those feelings, and with that acceptance came less reliance on alcohol. That pattern repeated itself over and over again, with alcoholics and people addicted to a wide spectrum of other drugs.

Chandler, Ben and Peri were only three of the hundreds of amazing stories my father told me over the years - stories of ordinary people who made life-altering breakthroughs in their ability to lead happy, productive lives and relate more lovingly to the people who shared their world. There was never a doubt in my mind that he was doing good work. I have rarely known anyone who had as much passion for his work as he did. All he ever wanted from his life was the ability to help people lead happier lives. He enjoyed the occasional recognition that came his way in later years, but no accolade or honor ever meant as much to him as a single human being telling him how much his knowledge, wisdom, and willingness to do this work had changed their lives. He surely left the world - and me - richer for having known him.

Henry Zeff

Henry Zeff - A son's tribute August 2003
As I sit to write this, I am looking at a photo of Leo with his full beard, at the height of his Guru stage. I don't know of any one else, personally, more qualified to wear the title of the Secret Chief. He was always a friend to anyone, at any hour of the day or night.

I remember many times, when I would be visiting overnight, the phone would ring with a late night call from a friend or a member of his extended family, in the middle of some personal problem, a bad trip, or whatever. Leo would answer, always with a soft voice no matter what the hour, and then with wisdom, humility, compassion, and Yiddish sayings. He was a master at work, rarely anxious, always patient and kind - to patients, friends, family and strangers alike.

My brother-in-law and his dad hadn't spoken a word in many years due to child/parent disagreements. Then at my sister-in-law's wedding, Leo spoke with the father for maybe a half hour and the father and son were able to converse as if they were old friends. The miracle at the wedding, I call it.

I don't know how many people's lives Leo touched like this and a thousand other ways throughout the years, in his profession as a psychologist, with and without the "materials" he used, and as a friend and caring person to all he knew.

His eagerness and excitement over each new material that became available was amazing. He was like a true scientist ever ready to check out another way to do the needed job.

His life was an amazing collection of experiences, from growing up dirt poor to finding a home in scouting and then the Army. To college and his degree in psychology, to the wild and crazy 60s, and then his version of a more peaceful, saner 60s. Then the 70's and the new materials of that age.

He was ever humble and quiet about his work and experimentation, even when he began to see the fruits of his work. He had to stay quiet; to be famous in his time was to cease to be able to help.

It is sweet to see Leo finally get some credit for the mark he made on the world of his time and the world to come as well. He truly was a Secret Chief.

"Andrew"

"Andrew" - An underground MDMA guide trained by Leo, early 2003
In the 1970's, I was living in California and was interested in personal, social, and spiritual paradigm change. So I asked somebody who was a role model for me in those regards, "Where can I have an experience with LSD?" She replied, "Oh, I thought you would never ask."

She introduced me to Leo. The protocol was not to volunteer information to people who might be interested. But if somebody asked and you sensed that the motivation was appropriate, you asked Leo for permission to share information in a more specific way. After recounting your personal experience to the person, they then might be introduced to Leo. I did a solo trip. LSD was the material during your introductory solo session. If you were a "good tripper" who could stay self-contained during your trip, then you might be invited to join the family. This meant that you could trip in a group of eight to twelve people on a weekend.

There were all kinds of people: doctors, lawyers, merchants, and marginal kinds such as a pornographer. But you had to have enough money to pay him, and you had to know somebody who was on this path to introduce you. You would pay a therapist's fee for the private introductory interview. You paid a couple hundred dollars for your initial trip, and the group trips cost less. Materials cost an additional ten to thirty dollars. Leo's model was to pay separately for the materials so people did not get greedy, thinking that more was better. People had to be told that after a certain dose they were going to get undesirable side effects rather than increased benefit. Some people needed to learn about that.

There were people in the family who had a harder time coming up with money. They participated on a work exchange basis. They did thorough housecleaning before the other participants arrived. The aesthetics of the setting were important to Leo. He thought if somebody opened their eyes during a bad trip and saw a lot of dust, that might not support the development of their soul as much as seeing flowers and a fresh candle.

Actually, Leo was not as visually oriented as me. When he was working in his disciple's house, there was a girlie calendar on the wall in the kitchen. I was the first person who said, "You know, this doesn't contribute to making me feel safe for tripping." We didn't talk about it at length, but he took it down.

There were a variety of materials that were available: mushrooms and mycelium, MDA, and ibogaine. We originally tripped at night because that is how indigenous people do it. For urban people that was quite a hardship. We did not have much time before and after a weekend. So Leo developed this daytime format so you would have time to come back from your trip in a completely rested state. People then had increasingly positive experiences. Now, a positive experience by Leo's standards was not what you experienced on the day of the trip. Leo believed the value of the medicine was what happened to your quality of life during the period that followed.

He made MDMA available to the group after he had experienced enough of it with Sasha Shulgin. By then, they felt confident that it was reasonable to introduce it to people like ourselves who were willing to experiment. Leo said every time that we are all experimenters. He emphasized that we did not know everything about these medicines, and although he was telling us the best that he knew, in fact nobody knew everything about them. One of my earliest trips was a mushroom trip. While coming down from the trip in that family setting, I got the very clear message "Do this every three months. Keep coming back even if you do not remember why." So I actually did it every three months for about five years.

Leo's groups had a consistent format. We sat around on Friday night in a talking circle. One by one, everybody told what was going on in their lives. If they had tripped before, they described what had happened to them since their last trip. You heard about a dozen stories, different issues that people were dealing with in their lives. You came to the realization that the nature of being human is to feel these struggles, contradictions, curiosities, longings, and pleasures.

Leo would review the instructions and the agreements. You were not to repeat to anybody where, when, or with whom you had this experience. You were not to leave the room without explicit permission from the facilitators. You would not do anything harmful to yourself or anyone else.

There was to be no sex with anybody else. The final agreement was Leo saying, "If I should at any time during the trip tell you to do something that you are not doing, or to stop something that you are doing, you will." He would look the person in the eye, and each participant would have to say "yes". Then Leo used to say "That means that if I told you to jump out a window, you would." He did not want it to seem like it would have to be something that would be clearly in our best interests, because in our tripping state it might seem like something that was against our best interests. So if he said, "Go fly now," we would say "Yes" without question.

Many people reported afterwards that it occurred to them during their trip to do inappropriate things. Then they remembered that they agreed not to do harm, and that they had agreed to do whatever they were told by the leader. Therefore, they would remember this and censor themselves. That turned out to be part of the freedom, not a restriction.

Not every group leader warrants being given that degree of trust. This sort of agreement was very delicate and strong. Then Leo would say to the group "I want you to know that I have never had to call on that, I have never invoked it, but you still need to agree to it because it is one of the agreements." Participants knew beforehand that every time they came they had to reaffirm the same commitment to the agreements. So the beginners in the group and the repeaters all came on a common playing field.

Then Leo gave advice. "If you don't know what to do and your mind wanders, then listen to the music. If you go into heavy judgments against yourself, then listen to the music." He instructed us not to interfere with other people's trips. This was altered for groups on MDMA, because Adam (MDMA) facilitates communication and compassionate connection.

After a lot of people in the family had experienced Adam, some people wanted to use it with softer agreements. There was a smaller group that met about once a month, just to take Adam. The MDMA group was less tightly structured than the family trips. For example, MDMA can have such sensuous body awareness that people wanted to be freer to be in each other's faces with the relational part. Participants in MDMA groups would have to ask a facilitator in order to have contact with anybody else. The facilitator would then ask the other person to see if it was okay for both people to communicate at that time. So there was physical (without being overtly sexual) as well as verbal contact between people in the MDMA group.

Leo looked at his notebook while going through this procedure each time. (Later I also used a notebook when I ran my groups.) The group could see they were in a carefully protected environment. This standardized routine enabled participants to be confident that they could go as deeply as possible into their trip, without having to keep part of their attention focused on their own safety or what was going on outside them.

There was also a small ritual to taking the medicine. We stood in a line waiting for Leo and his assistant to send us off, one by one, with a bon voyage hug. Leo gave good hugs. He was not in any hurry. He said he did not know how it worked, but people claimed they got something profound when he hugged them. He would say, "I've got plenty of it, so take all you need." It was an energy transmission, like recharging your battery. It was based on his confidence, his clarity, and his generosity. There was a humor about him. Yet at the same time he seemed like the group's father. He reminded me of my father, and he made us feel safe. At the end of your send-off hug, he said the same words year after year. He would say "Have a wonderful trip!" Then you took your medicine and you were on your own. You went to your place. You got your pad and your comforts ready. Some people were on ayahuasca, others mushrooms, others MDMA, or whatever.

When you started to come out of your trip in the afternoon, Leo served his homemade chopped chicken liver dish as the first food you would eat. He was an older Jewish man from a n Eastern European background, and he thought chopped chicken liver was the healthiest thing for you. He came around like a waiter with a platter of liver offering it to everybody. With a shorter acting material, like MDMA, some people were back by mid-day. Other people were still flat on their back and not yet ready to eat by supper. We were told not to talk about our trip that day. Everybody shared dinner. Then we went to bed.

Sunday morning there was a ritualized circle. Participants took turns describing what had happened during their trip. We would describe what we felt and did, in the manner of recounting a dream. But it was not about interpreting, except so far as the interpretation of it was part of the trip itself. Each participant would witness this incredible array of individual experiences that had occurred in the same room. You might see common threads and identify with someone else. Or somebody might seem uniquely different from you. Someone might even say "I can not remember anything because I have amnesia for my trip." This was the range of the human condition.

People would often be less judgmental toward themselves when they heard other people's stories. Similarly, people might learn new possibilities by looking at the variety of other people's experiences. When there was a sharing of experiences, somebody might come back three months later and say "When so-and-so said such-and-such in that circle, I took that home with me as part of my trip." Then Leo would say "Well yes, you were still in a somewhat altered state, even though you felt primarily returned, and it was part of your trip then."

We spontaneously used each other's learning. Certain experiences can be potentiated in a group setting, even while you are having your own inner journey. This is separate from any psychic ideas about shared tripping and group consciousness. Leo always encouraged people to have their own individual trip, although I know that some other groups got together with the purpose of working on group projects.

During the period when I was tripping regularly, I had a profound sense of community even with people I had never met, knowing that all over the world there were others who also knew that everything is connected. Bonds were made as our group developed. People fell in love and got married. Leo would say, "You don't want to make any life-changing decisions until at least three weeks after the trip. You don't want to move. You don't want to quit a job and take another one. You don't want to leave a relationship and start a new one. Just be with it a while. See what pertains to the trip itself and what is meant to be actualized in your life." That always seemed like good advice.

When somebody entered the family, they were given a small chalice. The glass cup had relief designs of blooming flowers on the silver stem and base. In the early days, Leo gave these to somebody who did the solo trip. They were from Mexico, and later they were not available anymore. Then a flat rolled silver version was distributed. So if you ever saw one of these cups in someone's house, then you knew they were in the same family. It was a symbolic way of recognizing when you were in the home of a family member. I later ran a group that had a comparable thing we distributed. After five years in Leo's group, I brought in my partner. While he valued the experience he did not like that particular setting. We both had facilitator skills and immediately wanted to share this process. The first time we hosted a group MDMA trip was in 1980. My partner asked me what I wanted for my birthday. I replied that I wanted to take MDMA together with some intimate friends. We chose about six people who we were close with or wanted to be closer to. He made the arrangements. The group went well. We had already developed a workshop circuit doing other kinds of personal development activities over in Europe. Therefore, we had access to a network of Gestalt therapists. Although they were not particularly interested in MDMA, they connected us with psychologists who we trained in West Germany. After getting to know and trust a few German psychologists, we told them about this new thing called MDMA. We invited them to share this experience with us. Then they wanted to invite some of their friends the next time that they came.

Our MDMA groups were this beneficial contribution that just sort of happened without planning. We were doing this regularly, primarily in Germany, but also Austria, Switzerland, Holland, Hungary, and Czechoslovakia. We started gradually in 1981. By the next year it really got going. We really had quite a community. Many participants returned at three-month intervals. Some brought along people who were significant in their lives.

There are a lot of retreat centers in Europe. Sometimes the people who provided these sites knew about our work and participated. Other times they had no idea what we were doing. We sat for about twenty groups of twenty people per year. That was 400 trips a year. Two thirds of those people were repeaters who were coming back. This continued until we stopped this work in 1988.

Our weekend workshops were completely based on Leo's model. There were only two changes to his protocol. First, we used only MDMA. We lived in America, but frequently visited Europe, so we would not be there to provide care afterwards. Therefore, we only used MDMA because it has a low incidence of prolonged reactions. If you sit for thousands of sessions, you do see some rough experiences.

The other change was that we did not personally interview everybody before the trip. The new people got cleared by the person who had been there before. If there were any concerns about the appropriateness of the new individual, such as health problems, then we would say, "No, we cannot take the risk." About a dozen psychologists from different cities became interested in starting their own groups. They seemed sufficiently mature, so they informally apprenticed with us. Once MDMA became freely accessible, I heard of people working with it who I wished were not. Still, I still think the lack of official control was more good than bad.

After experiencing MDMA, one of our clients talked for the first time to her parents about their experiences during World War II. This is a very big issue in Germanic Europe, with that older generation dying out with this great silence about the war. Another of our German clients was the daughter of a Nazi officer. She spent a lot of her childhood locked in a closet because he was a sadist, or did not know how to properly raise children. She was born with normal vision, yet became completely colorblind after prolonged isolation in the closet. As an adult she worked as an artist without being able to see color. She came to trip with us many times when she was in her thirties. She tripped hard, which is unusual on MDMA. She would vomit. She was terrified. She would think about suicide. One time while she was tripping, she decided that she wanted to die because it was too difficult.

That was the only instance in my experience when the quality of the sitting was extremely important for the outcome. I did not tell her not to kill herself; I just really stayed with her. She sometimes had a sense of breakthrough. Memories from childhood would come back to her. She returned to trip again three times a year for a year or two. We would ask her why she kept coming back if it was so unpleasant. She replied that she felt that she was, millimeter by millimeter, making progress. At one point while tripping she said, "I can see color!" From then on, her color blindness was cured.

"Katherine"

"Katherine" - July 7, 2003
I'd like to report a great experience I enjoyed in 1970 at Leo's home. In those days, if you were very lucky indeed, you might have been invited to participate in what was called a "guided trip." The idea was that under supervised conditions, psychedelics could provide an experience that mystics might work for years to be able to have.

On arrival, my husband and I were asked to do "withholds," an exercise that was meant to dispel any negative "charge" that we might have toward each other. Then Leo gave us some guidelines: we were not to leave the house, for our safety. We were not to engage in sex - that wasn't what this was about. We were each to have our own experience, and not disturb the other. We were there to take a look at the contents of our own minds, perhaps in a new light.

Well, all this sounded interesting and only mildly alarming, since Leo was a well-known and trusted friend. We lay on mats with blankets in front of his fireplace on his soft brown carpeting, looking up at a lovely bronze chandelier supported by a ceiling of natural wood. The large windows in the room looked out on his gardens, mostly big white shasta daisies. A stereo played soft popular music. Leo gave me a capsule containing large doses of both LSD and mescaline.

In a few minutes I felt myself relax and sigh, and it seemed the whole house sighed. The appearance of the room seemed to soften, and the chandelier took on the appearance of a glowing jewel. Tiny dust motes seemed to shine like diamonds in the air. I had never understood my early religious training; I just didn't understand what was meant by "God," and had no concept of what was holy at all. But now it seemed my surroundings had taken on new meaning, and shone with an inner light that seemed *self-evidently* sacred.

Later I seemed to pass through other gateways and worlds, some terrifying (I thought I was drowning in blood, and seemed to experience a friend's violent and terrible suicide) - and some oddly just disgusting: things appeared vulgar, sordid, and sort of plastic.

As I was struggling with this ugly world, Leo came over to me and he said simply "When you've come to the end of your rope, just let go."

I didn't just let go. I threw that rope from me, and leaped, I knew not to what!

Instantly I was transported into a state of utter bliss. I seemed to be able to look at this silly creature that was myself - forever setting traps for myself, stepping into them, and then actually being surprised! From my delightful distance, all this seemed hilarious in the extreme, and I laughed with real delight until Leo began to look at me anxiously again. He looked, with his gentle brown eyes, like a worried seal, and I laughed some more. Then I worried I might have hurt his feelings and stopped.

I went back to enjoying my surroundings. Jacob had put on some music that related to my Christian upbringing, and I enjoyed the hymns with some nostalgia. I amused myself by creating pretty visual effects and then changing them. I think at this point I was returning to "normal." After a time I realized I was "back," with considerable regret; I did not ever want to leave that joyful place.

Leo kindly helped us to shower, and we slept comfortably. I believe that I had a truly religious experience. For the first time I understood the nature of Heaven - being freed from my miserable self at last. Christ had said not to look for Heaven because it is all around us if we could only see it. Now I know what he meant - I've been there.

I think in psychedelic circles this is known as the experience of ego death. How odd that we should cling to something that is only a source of Misery.

Love to Leo!
A grateful student and friend

P.S. While I can't really judge how much this experience changed my life, I'm sure I'm much happier for it.

"Rachel"

"Rachel" - December 29, 2003
Leo, his wife, and his children were friends of my husband's mother from the synagogue up in Berkeley. My husband is the one who turned Leo onto marijuana.It was around May 1 of 1965 when we went to Leo's home, joined a group of other people, and had a group experience for the first time. My husband and I were the youngest people there. He was 30 and I was 25. It was a very interesting experience. I realized right away that most of the people were there to "get well" and there were some people with some severe problems. I did not have any that I knew about. I wanted to experience what was going on, and I did. One of the most interesting things that happened that night was we were all laid out in front of the fireplace downstairs and we had our earphones on and our eye shades on and then all of a sudden my husband sat up and called for Leo to come over. He said, "There is a woman upstairs way in the back. She's in trouble." Leo did not doubt him at all. He just went upstairs right where he said and that is where the woman was. She was in trouble. So we realized the power of what was going on. This was a powerful thing that we knew about but we had never experienced close up like that. That is how we met this woman, with whom we have been friends ever since.

There were things we wanted to know and that we wanted to experience. We felt we were perfect the way we were which included the potential for change. So Perfection is where we were coming from. We did not have it that we needed fixing. We had it that there were things we did not know - things we had not experienced that we wanted to. When I first came into this program, I had some doubt as to whether there was some getting well to do or not. As I experienced more of these trips, I realized that there was not. Then I came to the realization that there was more to do, more to experience, more to have, more to give. It was just more, and at the same time, there is only what there is right now. It is a funny juxtaposition. My favorite medicine without question was yage (ayahuasca). Yage and acid. That was my idea of a good time. It was a primitive sort of beast. You talk about dancing and the music becoming energy in your body - that is yage. I remember seeing power, tribal, witchcraft sort of things on that drug specifically. One time I was a lion and I looked down and saw this lion's paw. It was huge, I just felt the power of that lion in my paw, and I just knew how strong a lion was. It is primitive, quite basic and primal. My husband and I used the psychedelics as a way to experience more sensuality. I was able to feel a lot more pleasure from the use of psychedelics. It became a rule in Leo's work that there would be no sex taking place. I respected Leo for putting together a situation where you could have a large group of people on the medicine in a safe way. By having a set, a setting, a structure that people adhered to, it made it safe. I had an experience on mescaline and I remember that was all he had. I worried my way through half of the trip that I was going to waste the trip but then I settled down and I got with it. Then this music came floating through the air. I could see the notes and the clefs and then it just came. I was really going with it, then it started to go toward my crotch, and it turned into this snake. I snapped my legs shut, sat up and resisted it, which turned my life to shit. I just had the experience of resisting pleasure as not being a good thing and then I got back into my trip. I tried to get the snake back to make friends with the snake. Then the snake turned into an octopus. It was beckoning me. It took me down into the water and wanted me to come in a cave. I was scared but I went with it. He just wanted to show me where he lived. I also used LSD in the groups to break through my sensuality barriers, whatever they were, to have more sensuality. I have spirituality tied up with sensuality. We met in that realm. I always believed in God. I always had this secret kind of pleasure knowing that Leo was Jewish too. I felt that it was a very highly spiritual experience. All of it. I did not think you had to be sick to have spirituality. Many of those people did. One of the goals of the group was explained to us this way. America is a new country. It was only a couple of hundred years old and we have come a long way as a country. He and other people wanted to know if psychedelics would enable people to deal with rapidly changing realities. Could problems be solved quicker or more efficiently?

There were people in mathematics and architects brainstorming. There were tests going on about people who were stuck in places in their careers. Mathematicians, architects, chemists, artists, writers, and people who were stuck were given huge doses of mescaline and many of them just broke right through. So there were all kinds of things like that going on. Maybe this could be used for our country to go on in an efficient manner.Up until a few years ago, my husband and I would refer to Leo jokingly as the guy who ruined our lives. We were kidding. He had a lot to do with our lives. I would be a different person if I had not experienced what he had to offer. I feel blessed.

"Julia"

"Julia" - October 3, 2003
For my first experience, Leo had set the stage in his office. He changed that office into a bank of flowers with every symbol you could think of in there - the crucifix, the Star of David, the Hindu symbols, everywhere you looked there were symbols but mostly there were living, beautiful flowers all around. When I took the medicine, I lay back in this ordinary spot which he had made very comfortable for me with a little foam rubber mat and the ceiling was phony squares of insulation and they began to sparkle. Then I began to dissolve, then I'd come back around again. I died 10,000 times. At some point the dying stopped and I was in a neighborhood. I was in a place that was highly manicured and ordered. Nothing was happening. The lawns were cut, the shrubs were trimmed, the houses were perfect. There were little iron fences outside the windows. Nothing. It was dead as a doornail. I was trying to get out of that area because I did not like it. At that moment Leo lifted up the eye mask and said, "Where are you now?" Now in reality he could have been doing his office work and his bills at his desk there while I was going off some place, but he did check in and I said, "I'm stuck in the Midwest someplace and I can't get out." He said, "That's the way it should be. You should be there. Do not try to get out. Be there. Be there with it. Don't try to get out." At that moment the music changed from his usual warhorse scene which was romantic - Tchaikovsky to Handel's water music - and the conjunction of what he said and the music may have made a difference. I found myself on a hill overlooking a sparkling harbor and a city beneath it. I was dressed in tails and a top hat. I took my hat off of my head and made a big gesture over my head with my hand and lifted it off. Out of the hat came the most beautiful spray of stars you would believe. I laughed, and laughed. It was the beginning of change for me from being terribly depressed to another option.

I once overheard him say, "I became so sick of these people coming in with their depressions and their problems and offering other options and they're not being able to take any of them. I became so tired of that." Leo said he wouldn't say this until we were well into him and knowing the process.

In my group, people did seem to take other options. Most of them made significant changes. They were professional people. They didn't change really. When you meet them on the street you wouldn't see any changes, but in their lives they made different choices. When I was with Leo I was involved with a guy that I was bored with but he was good to me. My experience changed everything. I just couldn't take the boredom anymore. I still keep in touch with some of them. They are like family.

You know when you go home for Thanksgiving you've got those aunts and uncles. You know how they don't really fit in your life but they're there. That's family. At that time we were not the only people that were experimenting with this kind of thing. There were a lot of people out there experimenting and we all had this kind of bond. There was something beyond that was momentarily apparent and it led to a huge openness.

Leo made a difference in those people's lives - a big difference. Sure made a difference in mine, but it's interesting to be asked now because it's so integrated that it's hard to separate it and it's been so long ... Leo was such a leader. He had that military experience but he'd also had the experience of being a psychologist, being a Jew, being a Buddhist and being who he was and that combination made him such a fabulous leader. He provided some very strenuous structures on some people.

There was one woman who just could not stop talking. She'd engage you and then you'd be engaged and slowly you'd recognize that this thing was to go on for the next half hour. She was going to be right there in your face talking. It was never loud but terribly engaging and he saw it. He stayed with it for a couple of trips and then he finally said, "On this trip you are not allowed to talk at all." She was mad at him but she made some fabulous changes. She went from cosmetics to opening a massage school in San Francisco and became internationally known. She traveled all over the world with this business. My experiences with Leo affected my relationship with my own family as well. I would never have reunited with them in the same way. Leo started us off with pictures of ourselves before we ever took the medicine. In doing so, I had to write my mother and ask her for the pictures, and she sent me a whole suitcase full of these things from infancy all the way up to being a teenager. It gave me a window into her eyes and I saw my father holding me in a proud way. I've had a lot of differences with my father. They didn't end but it opened a door to beginnings.

"Laura"

"Laura"
My experience with Leo and his group intertwined with events that were part of the historical era itself and with other group experiences I had. I dropped LSD once before I met Leo and certainly would have found some other way to experiment with hallucinogens if I had not met him, as I was living on the cusp of the New York beatnik and California hippie worlds when I arrived in the San Francisco Bay area in 1965.

Leo's unique contribution to my life was his creation of a group within which it was possible to get agreement on what I experienced on hallucinogens. For this I am eternally grateful.

I first saw Leo after my first acid trip. I had arranged for a friend to "sit" with me. The trip started very well - I had read books about the psychedelic experience in preparation for my first trip, and my trip followed the experience as described in The Tibetan Book of the Dead by Leary, Alpert, and Metzner. However, my friend was not prepared to allow me the time and space to examine my own experience inwardly, and the end of the trip felt uncomfortable for us both. My friend referred me to Leo, and talking to him helped me to integrate the experiences of that first trip.

Leo's group trips added to the reality that seeing Leo alone had given me. The group setting nurtured a scientific approach to examining inner human experiences. The group gave me many opportunities to observe the experiences of others from the sidelines as well as through more intimate interactions. The group also gave me opportunities to have others tell me their observations of my trips, and provided opportunities to safely explore "hallucinations." For example, I saw a snake on a mat, knew intellectually that there was no snake, but had to get up and touch the spot that appeared to be a snake in order to have the "hallucination" end.

Leo's record-keeping gave me the opportunity to make scientific observations of the effects of different chemicals on perception and consciousness. We explored different doses, different substances and combinations of substances, taking "boosters " at various times during a trip, and, also using non-psychedelics such as Valium, Ritalin, and marijuana. I got to be expert enough to identify the type and combination of substances taken by observing my own experience and the behavior of others.

Beyond the "scientific" aspects, I experienced personal gratification in the areas of spirituality and musical awareness. I loved using earphones and appreciated the wide variety of music we listened to. In my profession at that time, social work, I became more attuned to the internal experiences of other people. Also, the weekends were just plain fun!

What is the aftermath of my experiences with Leo? For almost 40 years I, along with two friends I met at the group, have lived as part of a community. Within this last year one of my two friends died. I am at peace with death. This peace comes from having the reality of my own perfection and of the perfection of the universe I've created.

Appendix III: Resources

The books, websites and publications on the following pages are recommended for more information about psychedelic therapy and related topics. This list serves as an introduction and is by no means all-inclusive.

Evaluating the Scientific Literature

Like the Secret Chief, many therapists in the United States have surreptitiously employed psychedelic substances in spite of their illegality. Once they discovered the efficacy of such substances, they could not in good conscience withhold such effective means of treatment from their clients despite the risk of incarceration. One of the unfortunate consequences of this situation is that experiences and results cannot be publicly shared, which deprives current practitioners of a great deal of valuable information.

Nevertheless, there are many publications which present promising work with psychedelics, including dramatic help for tough cases that had been impervious to conventional forms of treatment. The World Wide Web Psychedelic Bibliography, available at www.maps.org/wwwpb, compiles a number of other bibliographies of psychedelic research and includes thousands of references, some with full text PDFs. These include the MAPS MDMA Literature Review Project (which includes full text PDFs of most papers), the Hofmann Collection (with over 4,000 psychedelic research papers from the late 1940s to the early 1970s, most with PDFs), and a number of other bibliographies. Other compilations are cited at the end of this section.

A major problem is to know how to evaluate the various references. Much of the current public misunderstanding is the result of the position of mainstream professionals and government agencies who have concentrated on emphasizing only the negative aspects of psychedelic use, screening out any data that would imply usefulness. Dr. Roger Walsh [2] comments on the selective bias of public information:

> Barriers to research and publication appear to have resulted in a bias toward selective dissemination of predominantly negative information about the effects of psychedelics...
>
> There have probably been few areas in psychology that have been subject to as much misinformation and sensationalistic reporting by the media as psychedelic experiences. While preliminary clinical research suggested that they might have considerable research and clinical potential, the popular press preoccupied itself almost entirely with sensationalistic accounts of dangers. This media treatment soon resulted in the cessation of almost all research and a bias at many levels of society toward the dissemination of only negative reports...
>
> ...What seemed to be widely unrecognized was that large numbers of people appeared to have derived, at least from their own point of view, significant benefits from psychedelics, a situation markedly at variance with media accounts of their devastating effects.

In this same paper, Walsh describes submitting a paper to a reputable professional journal that included evidence suggesting that in some cases, people might find psychedelics beneficial. Surprisingly, the editor responded that the paper could be accepted only if any reference to positive effects of psychedelics was removed. Since this was a fairly open-minded editor, Walsh wonders at the chance of publication of positive statements in other places.

To clarify the various positions held, it may be helpful to refer to recent writing which sheds light on the conflicting perceptions of those who claim to be experts. The problem is that mainstream science holds a very limited view of the nature of the human being. Clarification of this situation is now being presented in the relatively new field of Transpersonal Psychology, which recognizes those aspects of human experience in which the sense of identity of self extends beyond the individual or personal to encompass wider aspects of humankind - life, psyche, and cosmos - validating the spiritual foundation of life. An overview of many of the aspects of transpersonal psychology is presented in the book *Paths Beyond Ego: The Transpersonal Vision*[3], a compilation of articles by over thirty contributors knowledgeable in this field.

An extraordinarily comprehensive overview of all aspects of human development is presented by Ken Wilber in *Sex, Ecology, Spirituality: The Spirit of Evolution*[4] and in more readable form in *A Brief History of Everything*[5]. To again quote Walsh, a leading authority in the field of Transpersonal Psychology[6]:

> The aim of these two books is to trace evolution - physical, biological, and human - and to set it within the context of the perennial philosophy: the common core of wisdom at the heart of the great religious traditions. Human evolution - of brain and mind, society and culture - is traced from early hominids to today and related to phenomena such as the evolution of gender relationships , human relationship to the earth, technology, philosophy, religion, and more.
>
> The scope of the work is extraordinary. Only a handful of thinkers, such as Aurobindo in the East and Hegel in the West, have assembled such evolutionary visions. Yet Wilber's view is unique in not only providing a far reaching vision but also grounding that vision in contemporary research in fields such as cosmology, biology, anthropology, sociology, psychology, philosophy, and ecology.

The crux of the most serious disagreements among psychedelic investigators is the value placed on objective experience versus subjective experience. Mainstream science, through the dictum "if it can't be measured, it's not science," by and large ignores subjective or interior experience in favor of the objective outside world. This leaves them living in, according to Wilber[5], a "monological" world, or "flatland." In such a world, much of that which is of great value to humans is nonexistent, such as the very essence of consciousness and the nature of the human mind. It is precisely these latter elements that are so effectively revealed through appropriate use of psychedelics. It is worth reading *A Brief History of Everything*[5] to observe how all aspects of humanity and life can be put into perspective, a perspective developed by a brilliant mind that has carefully examined the data from many areas of scientific research, as well as the world's spiritual disciplines.

With a chemical such as LSD, which opens up access to vast dimensions of the human mind, it should be clear that those who have not taken the chemical or who have not reached transpersonal levels of experience are in a poor position to evaluate the potential of psychedelics and their numerous applications. Consequently, while a great number of investigations were conducted over the years, the outcomes vary considerably depending on the experience and qualities of the investigator. Some investigators conducted research to specifically debunk claims made for the use of LSD. Since set and setting have been found to be eminently definitive factors in the outcome of psychedelic experiences, the experiences of subjects are highly colored by the attitude and belief system of the investigator, particularly with naive subjects. It is therefore important in evaluating published papers to be aware of the qualifications and position of the investigator. The difference in outcome with unskilled supervision can be like using a large amphibious airplane to get from place to place by taxiing around in the water without realizing that it can take off and fly.

The diversity of viewpoints revealed by examining the literature can be appreciated by pondering the label attached to psychedelics by some members of the medical profession, "psychotomimetic" (psychosis mimicking). Another term widely adopted by the medical profession is the term "hallucinogens," which is often used in a deprecatory manner. Those who originated the term psychotomimetic most likely were unable to distinguish between the disorienting and illuminating aspects of the psychedelic experience, or had no personal experience with LSD, or else had uncomfortable personal experiences. It is now well recognized by seasoned psychedelic practitioners that a major requirement for a rewarding experience is honesty, whereby one willingly and fruitfully confronts and resolves any uncomfortable feelings being experienced. Through such confrontation, much valuable learning takes place. The extensive work of Jacob and others in the field indicates that one of the major causes of discomfort while taking psychedelics is the subject's attempt to maintain an image of him/herself that is not in harmony with one's authentic self. The greater the investment in the created image - and consequently, the greater the reluctance to change - the greater the discomfort. The disparity can be so great and so painful that the subject employs psychotic episodes to escape the discomfort. This is part of the reason that some members of the medical profession have chosen the term "psychotomimetic" to describe the action of drugs like LSD.

I have concluded that a more accurate term is "psychosis releasing," as the action of a psychedelic often focuses on those areas in the unconscious that most demand resolution. The willingness to surrender to the experience and allow such resolution to proceed often results in the most valuable kind of learning about one's repressed feelings, hidden values, compulsions and aspirations, and inappropriate behavior. In addition, as repressed psychic material is discharged, the inner core of our transpersonal nature can manifest. This can lead to profound and ecstatic realization of the true nature of ourself and the cosmos.

It is interesting that it is the group that prefers the psychotomimetic label for psychedelics whose professional opinion has been accepted by many media and government officials. This outcome may perhaps be accounted for because many mainstream scientists are very unsettled by the fact that among the most outstanding experiences of psychedelics is the discovery of the presence of Divinity and the sacredness of life. In the current Western world, our scientists are the most respected source of truth, even though polls show that over 90% of the American population believes in God.

For some reason, which I am sure has complex roots, many mainstream psychiatrists and government officials prefer to discount the opinions of those who are truly qualified. Their position may have been greatly influenced by the proselytizing of the Tim Learys of the world, and the unacceptable antics of many young people abusing psychedelic substances. There may also be an aversion to persons truly enjoying themselves, which seems to be frowned upon by many puritanical Americans. But this does not excuse them from objectively examining and appraising all the data, nor from recognizing the appropriate credentials of those qualified to evaluate the use of psychedelics. A well balanced summary of psychedelic therapy research is contained in Grinspoon and Bakalar's book Psychedelic Drugs Reconsidered[7] in the chapter on Therapeutic Uses. Their conclusions at the end of the chapter, including their suggestions for further study, are well worth noting.
